| $f_{wc}$   | Fraction of total water body COPC concentration in the water column          | unitless | <p style="text-align: center;"><b>0 to 1 (calculated - Table B-2-10)</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-10.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default variable values recommended for use in Table B-2-10 may not accurately represent site-specific water body conditions. However, the ranges of several variables—including <math>d_{bs}</math>, and <math>\theta_{bs}</math> - is relatively narrow; therefore, the uncertainty is expected to be relatively small. Other variables, such as <math>d_{wc}</math> and <math>d_z</math>, can be reasonably estimated on the basis of generally available information. The largest degree of uncertainty may be introduced by the default medium specific OC content values. OC content values are often not readily available and can vary widely for different locations in the same medium. Therefore, default values may not adequately represent site-specific conditions.</p>                                                                                                                           |
| $C_{wtot}$ | Total water body COPC concentration, including water column and bed sediment | mg/L     | <p style="text-align: center;"><b>Varies (calculated - Table B-2-9)</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-9.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default variable values recommended for use in the equation in Table B-2-9 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with variables <math>Vf_{xs}</math>, <math>A_w</math>, <math>d_{wc}</math>, and <math>d_{bs}</math> is expected to be limited either because the probable ranges for variables are narrow or information allowing accurate estimates is generally available. Uncertainty associated with <math>f_{wc}</math> is largely the result of water body associated with default OC content values, and may be significant in specific instances. Uncertainties associated with the total COPC load into water body (<math>L_T</math>) and overall total water body COPC dissipation rate constant (<math>k_{wt}</math>) may also be significant in some instances because of the summation of many variable-specific uncertainties.</p> |

TABLE B-2-17

(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 3 of 4)

| Variable | Description                           | Units | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------|---------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $d_{wc}$ | Depth of water column                 | m     | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific, and should be an average annual value.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Use of default values for depth of water column, <math>d_{wc}</math>, may not accurately reflect site-specific water body conditions. Therefore, use of default values may contribute to the under- or overestimation of <math>C_{wctot}</math>. However, the degree of uncertainty associated with this variable is expected to be limited, because information regarding this variable is generally available.</p>                                                                                                                                           |
| $d_{bs}$ | Depth of upper benthic sediment layer | m     | <p style="text-align: center;"><b>0.03</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends a default upper-benthic sediment depth of 0.03 meter, which is based on the center of this range cited by U.S. EPA (1993a; 1993b). This range is consistent with U.S. EPA (1994).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended default value for depth of upper benthic layer, <math>d_{bs}</math>, may not accurately represent site-specific water body conditions. Therefore, use of this default value may contribute to the under- or overestimation of <math>C_{wctot}</math>. However, the degree of uncertainty associated with this variable is expected to be limited because of the narrow recommended range.</p> |

## TABLE B-2-17

### TOTAL WATER COLUMN CONCENTRATION (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 4 of 4)

#### REFERENCES AND DISCUSSION

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is cited as one of the sources of the range of  $d_{bs}$  values. This document cites U.S. EPA (1993a) as its source.

U.S. EPA. 1993a. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document is cited by U.S. EPA (1994) and NC DEHNR (1997) as one of the sources of the ranges of  $d_{bs}$  values. No original source of this range was identified.

U.S. EPA. 1993b. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November.

This document states that the upper benthic sediment depth,  $d_{bs}$ , representing the portion of the bed in equilibrium with the water column, cannot be precisely specified. However, the document states that values from 0.01 to 0.05 meter would be appropriate.

U.S. EPA. 1994. *Draft Guidance for Performing Screening Level Risk Analyses at Combustor Facilities Burning Hazardous Waste. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facility*. April 15.

This document is cited as one of the reference sources for the default value for depth of upper benthic layer ( $d_{bs}$ ). The recommended value is the midpoint of an acceptable range. This document cites U.S. EPA (1993a) as the source of its information. The degree of uncertainty associated with the variables  $d_{wc}$  and  $d_{bs}$  is expected to be minimal either because information for estimating these variables is generally available ( $d_{wc}$ ) or the probable range for a variable ( $d_{bs}$ ) is narrow. Uncertainty associated with the variables  $f_{wc}$  and  $C_{wtot}$  is largely associated with the use of default OC content values. Because OC content is known to vary widely in different locations in the same medium, use of default medium-specific values can result in significant uncertainty in some instances.

TABLE B-2-18

**DISSOLVED PHASE WATER CONCENTRATION  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 3)

**Description**

This equation calculates the concentration of contaminant dissolved in the water column.

Uncertainties associated with this equation include the following:

- (1) The variables in Table B-2-18 are site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of  $C_{dw}$ . The uncertainty associated with the variables  $C_{wCTOT}$  and  $Kd_{sw}$  is associated with estimates of *OC* content. Because *OC* content values can vary widely for different locations in the same medium, using default *OC* values may result in significant uncertainty in specific cases.

**Equation**

$$C_{dw} = \frac{C_{wctot}}{1 + Kd_{sw} \cdot TSS \cdot 10^{-6}}$$

**For mercury modeling:**

Dissolved phase water concentration is calculated for divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) using their respective  $C_{wctot}$  values and  $Kd_{sw}$  values.

| Variable  | Description                         | Units | Value |
|-----------|-------------------------------------|-------|-------|
| $C_{dw}$  | Dissolved phase water concentration | mg/L  |       |
| $10^{-6}$ | Units conversion factor             | kg/mg |       |

TABLE B-2-18

U.S. EPA OSW recommends the use of site- and waterbody specific measured values, representative of long-term average annual values for the water body of concern (see Chapter 5). A value of 10 mg/L was cited by NC DEHNR (1997), U.S. EPA (1993a), and U.S. EPA (1993b) in the absence of site-specific measured data.</p> <p>The following uncertainty is associated with this variable:</p> <p>Limitation on measured data used for determining a water body specific total suspended solids (TSS) value may not accurately reflect site- and water body-specific conditions long term. Therefore, the TSS value may contribute to the under-or overestimation of <math>f_{wc}</math>.</p>                                                                                                                                                                                                                                                                                                                                                                             |

## TABLE B-2-18

### DISSOLVED PHASE WATER CONCENTRATION (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 3 of 3)

#### REFERENCES AND DISCUSSION

NC DEHNR 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is cited as one of the sources for  $Kd_s$  values and a default TSS value of 10. This document cites (1) U.S. EPA (1993a; 1993b) as its sources of information regarding TSS, and (2) RTI (1992) as its source regarding  $Kd_s$ .

U.S. EPA. 1993a. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document is cited by U.S. EPA (1994) and NC DEHNR (1997) as one of the sources of the range of  $Kd_s$  value and the assumed OC value of 0.075 for surface water. The generic equation for calculating partition coefficients (soil, surface water, and bed sediments) is as follows:  $Kd_{ij} = K_{ocj} * OC_i$ .  $K_{oc}$  is a chemical-specific value; however, OC is medium-specific. The range of  $Kd_s$  values was based on an assumed OC value of 0.01 for soil. Therefore, the  $Kd_{sw}$  values were estimated by multiplying the  $Kd_s$  values by 7.5, because the OC value for surface water is 7.5 times greater than the OC value for soil. This document is also cited by U.S. EPA (1994) and NC DEHNR (1997) as the source of the recommended TSS value.

U.S. EPA. 1993b. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. November.

This document is cited by U.S. EPA (1994) and NC DEHNR (1997) as one of the sources of the range of  $Kd_s$  value and the assumed OC value of 0.075 for surface water. The generic equation for calculating partition coefficients is as follows:  $Kd_{ij} = K_{ocj} * OC_i$ .  $K_{oc}$  is a chemical-specific value; however, OC is medium-specific. The range of  $Kd_s$  values was based on an assumed OC value of 0.01 for soil. Therefore, the  $Kd_{sw}$  values were estimated by multiplying the  $Kd_s$  values by 7.5, because the OC value for surface water is 7.5 times greater than the OC value for soil. This document is also cited by U.S. EPA (1994) and NC DEHNR (1997) as the source of the recommended TSS value.

U.S. EPA. 1994. *Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Waste. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. April 15.

This document is cited as one of the sources of the range of  $Kd_s$  values, citing RTI (1992) as its source of information.

TABLE B-2-19

**COPC CONCENTRATION IN BED SEDIMENT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 4)

**Description**

This equation calculates the COPC concentration in bed sediments.

Uncertainties associated with this equation include the following:

- (1) The default variable values recommended for use in the equation in Table B-2-19 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with variables  $\theta_{bs}$ ,  $BS$ ,  $d_{wc}$ , and  $d_{bs}$  is expected to be limited either because the probable ranges for these variables are narrow or because information allowing reasonable estimates is generally available.
- (2) Uncertainties associated with variables  $f_{bs}$ ,  $C_{wtot}$  and  $Kd_{bs}$  are largely associated with the use of default *OC* content values in their calculation. The uncertainty may be significant in specific instances, because *OC* content is known to vary widely in different locations in the same medium.

**Equation**

$$C_{sed} = f_{bs} \cdot C_{wtot} \cdot \frac{Kd_{bs}}{\theta_{bs} + Kd_{bs} \cdot BS} \cdot \frac{d_{wc} + d_{bs}}{d_{bs}}$$

**For mercury modeling':**

COPC concentration in bed sediment is calculated for divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) using their respective  $C_{wtot}$  values;  $f_{bs}$  values; and  $Kd_{bs}$  values.

| Variable  | Description                                                         | Units    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|---------------------------------------------------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{sed}$ | COPC concentration in bed sediment                                  | mg/kg    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| $f_{bs}$  | Fraction of total water body COPC concentration in benthic sediment | unitless | <p style="text-align: center;"><b>Varies (calculated - Table B-2-10)</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-10.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The default values for the variables in Table B-2-10 may not accurately represent site- and water body-specific conditions. However, the range of several variables—including <math>d_{bs}</math>, <math>BS</math>, and <math>\theta_{bs}</math>—is relatively narrow. Other variables, such as <math>d_{wc}</math> and <math>d_{zs}</math>, can be reasonably estimated on the basis of generally available information. The largest degree of uncertainty may be introduced by the default medium-specific <i>OC</i> content values. Because <i>OC</i> content values may vary widely in different locations in the same medium, by using default values may result in significant uncertainty in specific cases.</li> </ol> |

TABLE B-2-19

**COPC CONCENTRATION IN BED SEDIMENT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 2 of 4)

| Variable      | Description                                                                  | Units                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|------------------------------------------------------------------------------|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wtot}$    | Total water body COPC concentration, including water column and bed sediment | mg/L                     | <p style="text-align: center;"><b>Varies (calculated - Table B-2-9)</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-9.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The default variable values recommended for use in the equation in Table B-2-9 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with variables <math>V_{fx}</math>, <math>A_w</math>, <math>d_{wc}</math>, and <math>d_{bs}</math> is expected to be limited either because the probable ranges for these variables are narrow or information allowing reasonable estimates is generally available.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>k_{wt}</math> may also be significant because of the summation of many variable-specific uncertainties.</li> </ol> |
| $Kd_{bs}$     | Bed sediment/sediment pore water partition coefficient                       | L/kg                     | <p style="text-align: center;"><b>Varies (see Appendix A-2)</b></p> <p>This variable is COPC-specific, and should be determined from the COPC tables in Appendix A-2.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The default range (8 to 2,100,000 L/kg) of <math>Kd_{bs}</math> values are based on default OC content values for sediment and soil. Because medium-specific OC content may vary widely at different locations in the same medium, the uncertainty associated with <math>Kd_{bs}</math> values calculated by using default OC content values may be significant in specific instances.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| $\theta_{bs}$ | Bed sediment porosity                                                        | $L_{water}/L_{sediment}$ | <p style="text-align: center;"><b>0.4 to 0.8</b><br/><b>Default: 0.6</b></p> <p>This variable is site-specific. U.S. EPAOSW recommends a default bed sediment porosity of 0.6 (by using a BS value of 1 g/cm<sup>3</sup> and a solids density [<math>\rho_s</math>] value of 2.65 kg/L), calculated by using the following equation (U.S. EPA 1993a):</p> $\theta_{bs} = 1 - BS / \rho_s$ <p>This is consistent with other U.S. EPA (1993b and 1994) guidance.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) To the extent that the recommended default values of BS and <math>\rho_s</math> do not accurately represent site- and water body-specific conditions, <math>\theta_{bs}</math> will be under- or overestimated to some degree. However, the degree of uncertainty is expected to be minimal, based on the narrow range of recommended values.</li> </ol>                                                                                                                                                                                                       |

TABLE B-2-19

**COPC CONCENTRATION IN BED SEDIMENT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 3 of 4)

| Variable | Description                           | Units           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------|---------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $BS$     | Benthic solids concentration          | $\text{g/cm}^3$ | <p style="text-align: center;"><b>0.5 to 1.5</b><br/><b>Default: 1.0</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends a default value of 1.0, consistent with U.S. EPA (1993a), which states that this value should be reasonable for most applications. No reference is cited for this recommendation. This is also consistent with other U.S. EPA (1993b and 1994) guidance.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended default value for <math>BS</math> may not accurately represent site- and water body-specific conditions. Therefore, the variable <math>C_{sed}</math> may be under- or overestimated to a limited degree, as indicated by the narrow range of recommended values.</p> |
| $d_{wc}$ | Depth of water column                 | m               | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Use of default <math>d_{wc}</math> values may not accurately reflect site-specific conditions. Therefore, use of these default values may contribute to the under- or overestimation of the variable <math>C_{sed}</math>. However, the degree of uncertainty is expected to be minimal, because resources allowing reasonable water body-specific estimates of <math>d_{wc}</math> are generally available.</p>                                                                                                                                                                   |
| $d_{bs}$ | Depth of upper benthic sediment layer | m               | <p style="text-align: center;"><b>0.03</b></p> <p>This variable is site-specific. U.S. EPA recommends a default upper-benthic sediment depth of 0.03 meter, which is based on the center of this range cited by U.S. EPA (1993b). This is consistent with U.S. EPA (1994) and NC DEHNR (1997).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Use of default <math>d_{bs}</math> values may not accurately reflect site-specific conditions. Therefore, use of these values may contribute to the under- or overestimation of the variable <math>C_{sed}</math>. However, the degree of uncertainty is expected to be small, based on the narrow recommended range of default values.</p>                                             |

## TABLE B-2-19

### COPC CONCENTRATION IN BED SEDIMENT (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 4 of 4)

#### REFERENCES AND DISCUSSION

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is cited as one of the reference source documents for the default value for bed sediment porosity ( $\theta_{bs}$ ). This document cites U.S. EPA (1993a; 1993b) as its source of information. This document is also cited as one of the reference source documents for the default value for depth of the upper benthic layer. The default value is the midpoint of an acceptable range. This document cites U.S. EPA (1993a; 1993b) as its source of information for the range of values for the depth of the upper benthic layer. This document is also cited as one of the reference source documents for the default benthic solids concentration ( $BS$ ).

U.S. EPA. 1993a. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November 1993.

This document is cited by U.S. EPA (1994) and NC DEHNR (1997) as one of the sources of the range of  $Kd_s$  values and an assumed  $OC$  value of 0.04 for sediment. The generic equation for calculating partition coefficients (soil, surface water, and bed sediments) is as follows:  $Kd_{ij} = K_{oc} * OC_i$ .  $K_{oc}$  is a chemical-specific value; however,  $OC$  is medium-specific. The range of  $Kd_s$  values was based on an assumed  $OC$  value of 0.01 for soil. Therefore, the  $Kd_{bs}$  value was estimated by multiplying the  $Kd_s$  values by 4, because the  $OC$  value for sediment is four times greater than the  $OC$  value for soil. This document is also cited as the source of the equation for calculating bed sediment porosity ( $\theta_{bs}$ ). No source of this equation was identified. This document was also cited as the source for the range of the benthic solids concentration ( $BS$ ). No source of this range was identified.

U.S. EPA. 1993b. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document is cited by NC DEHNR (1997) and U.S. EPA (1994) as the source of the default bed sediment porosity value ( $\theta_{bs}$ ), the default benthic solids concentration value ( $BS$ ), and the range for depth of upper benthic layer ( $d_{bs}$ ) values.

U.S. EPA. 1994. *Draft Guidance for Performing Screening Level Risk Analyses at Combustor Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. April 15.

This document is cited as one of the sources of the range of  $Kd_s$  values and an assumed  $OC$  value of 0.04 for sediment. This document cites RTI (1992) as its source of information regarding  $Kd_s$  values. This document is cited as one of the reference source documents for the default value for bed sediment porosity ( $\theta_{bs}$ ). This document cites U.S. EPA (1993a; 1993b) as its source. This document is also cited as one of the reference source documents for the default value for depth of upper benthic layer ( $d_{bs}$ ). The default value is the midpoint of an acceptable range. This document cites U.S. EPA (1993a; 1993b) as its source of information for the range of values for the depth of the upper benthic layer. This document is also cited as one of the reference source documents for the default benthic solids concentration ( $BS$ ).

TABLE B-3-1

**PLANT CONCENTRATION DUE TO DIRECT DEPOSITION  
(TERRESTRIAL PLANT EQUATIONS)**

(Page 1 of 10)

**Description**

This equation calculates the COPC concentration in plants, resulting from wet and dry deposition of particle phase COPCs onto the exposed plant surface.

The limitations and uncertainty associated with calculating this value include the following:

- (1) Uncertainties associated with the variables  $Q$ ,  $Dydp$ , and  $Dywp$  are site-specific.
- (2) The calculation of  $kp$  values does not consider chemical degradation processes. Inclusion of chemical degradation process would decrease the amount of time that a compound remains on plant surfaces (half-time) and thereby increase  $kp$  values.  $Pd$  decreases with increased  $kp$  values. Reduction of half-time from the assumed 14 days to 2.8 days, for example, would decrease  $Pd$  about 5-fold.
- (3) The calculation of other parameter values (for example,  $Fw$  and  $Rp$ ) is based directly or indirectly on studies of specific types of vegetation (primarily grasses and forbes). To the extent that the calculated parameter values do not accurately represent all site-specific forage species, uncertainty is introduced.
- (4) The uncertainties associated with the variables  $F_v$ ,  $Tp$ , and  $Yp$  are not expected to be significant.

**Equation**

$$Pd = \frac{1000 \cdot Q \cdot (1 - F_v) \cdot [Dydp + (Fw \cdot Dywp)] \cdot Rp \cdot [1.0 - \exp(-kp \cdot Tp)] \cdot 0.12}{Yp \cdot kp}$$

**For mercury modeling:**

$$Pd_{Mercury} = \frac{1000 \cdot (0.48Q_{TotalMercury}) \cdot (1 - F_{v_{Hg^{2+}}}) \cdot [Dydp + (Fw \cdot Dywp)] \cdot Rp \cdot [1.0 - \exp(-kp \cdot Tp)] \cdot 0.12}{Yp \cdot kp}$$

In calculating  $Pd$  for mercury compounds,  $Pd(Mercury)$  is calculated as shown above using the total mercury emission rate ( $Q$ ) measured at the stack and  $F_v$  for mercuric chloride ( $F_v = 0.85$ ). As presented below, the calculated  $Pd(Mercury)$  value is apportioned into the divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) forms based on a 78%  $Hg^{2+}$  and 22% MHg speciation split in plants (see Chapter 2).

$$\begin{aligned} Pd(Hg^{2+}) &= 0.78 Pd(Mercury) \\ Pd(MHg) &= 0.22 Pd(Mercury) \end{aligned}$$

After calculating species specific  $Pd$  values, divalent and methyl mercury should continue to be modeled throughout Appendix B equations as individual COPCs.

| $F_v$    | Fraction of COPC air concentration in vapor phase          | unitless             | <p align="center"><b>0 to 1 (see Appendix A-2)</b></p> <p>This variable is COPC-specific and should be determined from the COPC tables in Appendix A-2.</p> <p>Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) Calculation is based on an assumption of a default <math>S_T</math> value for background plus local sources, rather than an <math>S_T</math> value for urban sources. If a specific site is located in an urban area, the use of the latter <math>S_T</math> value may be more appropriate. Specifically, the <math>S_T</math> value for urban sources is about one order of magnitude greater than that for background plus local sources and would result in a lower calculated <math>F_v</math> value; however, the <math>F_v</math> value is likely to be only a few percent lower.</li> <li>(2) According to Bidleman (1988), the equation used to calculate <math>F_v</math> assumes that the variable <math>c</math> is constant for all chemicals; however, the value of <math>c</math> depends on the chemical (sorbate) molecular weight, the surface concentration for monolayer coverage, and the difference between the heat of desorption from the particle surface and the heat of vaporization of the liquid-phase sorbate. To the extent that site- or COPC-specific conditions may cause the value of <math>c</math> to vary, uncertainty is introduced if a constant value of <math>c</math> is used to calculate <math>F_v</math>.</li> </ol> |
| $Dydp$   | Unitized yearly average dry deposition from particle phase | s/m <sup>2</sup> -yr | <p align="center"><b>Varies (modeled)</b></p> <p>This variable is COPC- and site-specific, and is determined by air dispersion modeling (see Chapter 3). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Variable | Description                                          | Units    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|------------------------------------------------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $R_p$    | Interception fraction of the edible portion of plant | unitless | <p align="center"><b>0.5</b></p> <p>U.S. EPA OSW recommends the use of the <math>R_p</math> value of 0.5 , which is consistent with the value used by U.S. EPA (1994b; 1995) in development of values for the fraction of deposition that adheres to plant surfaces, <math>F_w</math>, for forage. As summarized in Baes, Sharp, Sjoeren, and Shor (1984), experimental studies of pasture grasses identified a correlation between initial <math>R_p</math> values and productivity (standing crop biomass [ <math>Y_p</math>]) (Chamberlain 1970):</p> $R_p = 1 - e^{-\gamma \cdot Y_p}$ <p>where:</p> <p><math>R_p</math> = Interception fraction of edible portion of plant (unitless)</p> <p><math>\gamma</math> = Empirical constant; Chamberlain (1970) presents a range of 2.3 to 3.3; Baes, Sharp, Sjoeren, and Shor (1984) uses the midpoint, 2.88, for pasture grasses.</p> <p><math>Y_p</math> = Yield or standing crop biomass (productivity) (kg DW/m<sup>2</sup>)</p> <p>Baes, Sharp, Sjoeren, and Shor (1984) proposed using the same empirical relationship developed by Chamberlain (1970) for other vegetation classes. Class-specific estimates of the empirical constant, <math>\gamma</math>, were developed by forcing an exponential regression equation through several points, including average and theoretical maximum estimates of <math>R_p</math> and <math>Y_p</math> (Baes, Sharp, Sjoeren, and Shor 1984).</p> <p>Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) The empirical relationship developed by Chamberlain (1970) on the basis of a study of pasture grass may not accurately represent all forage varieties of plants.</li> <li>(2) The empirical constants developed by Baes, Sharp, Sjoeren, and Shor (1984) for use in the empirical relationship developed by Chamberlain (1970) may not accurately represent site-specific mixes of plants.</li> </ol> |

| Variable    | Description                                                    | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Fw</i>   | Fraction of COPC wet deposition that adheres to plant surfaces | unitless             | <p align="center"><b>Anions: 0.20</b><br/><b>Cations and most Organics: 0.6</b></p> <p>Consistent with U.S. EPA (194b; 1995) in evaluating aboveground forage, U.S. EPA OSW recommends using the value of 0.2 for anions and 0.6 for cations and most organics. These values are the best available information, based on a review of the current scientific literature, with the following exception: U.S. EPA OSW recommends using an <i>Fw</i> value of 0.2 for the three organic COPC that ionize to anionic forms. These include (1) 4-chloroaniline, (2) n-nitrosodiphenylamine, and (3) n-nitrosodi-n-propylamine (see Appendix A-2).</p> <p>The values estimated by U.S. EPA (1994b; 1995) are based on information presented in Hoffman, Thiessen, Frank, and Blaylock (1992), which presented values for a parameter (<i>r</i>) termed the "interception fraction." These values were based on a study in which soluble radionuclides and insoluble particles labeled with radionuclides were deposited onto pasture grass (specifically a combination of fescues, clover, and old field vegetation) via simulated rain. The parameter (<i>r</i>) is defined as "the fraction of material in rain intercepted by vegetation and initially retained" or, essentially, the product of <i>Rp</i> and <i>Fw</i>, as defined for use in this guidance:</p> $r = Rp \cdot Fw$ <p>The <i>r</i> values developed by Hoffman, Thiessen, Frank, and Blaylock (1992) were divided by an <i>Rp</i> value of 0.5 for forage (U.S. EPA 1994b). The <i>Fw</i> values developed by U.S. EPA (1994b) are 0.2 for anions and 0.6 for cations and insoluble particles. U.S. EPA (1994b; 1995) recommended using the <i>Fw</i> value calculated by using the <i>r</i> value for insoluble particles to represent organic compounds; however, no rationale for this recommendation is provided.</p> <p>Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) Values of <i>r</i> developed experimentally for pasture grass (specifically a combination of fescues, clover, and old field vegetation) may not accurately represent all forage varieties specific to a site.</li> <li>(2) Values of <i>r</i> assumed for most organic compounds, based on the behavior of insoluble polystyrene microspheres tagged with radionuclides, may not accurately represent the behavior of organic compounds under site-specific conditions.</li> </ol> |
| <i>Dywp</i> | Unitized yearly average wet deposition from particle phase     | s/m <sup>2</sup> -yr | <p align="center"><b>Varies (modeled)</b></p> <p>This variable is COPC- and site-specific, and is determined by air dispersion modeling (see Chapter 3). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|----------|--------------------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $kp$     | Plant surface loss coefficient | $\text{yr}^{-1}$ | <p align="center"><b>18</b></p> <p>U.S. EPA OSW recommends the <math>kp</math> value of 18 recommended by U.S. EPA (1993; 1994b). The <math>kp</math> value selected is the midpoint of a possible range of values. U.S. EPA (1990) identified several processes—including wind removal, water removal, and growth dilution—that reduce the amount of contaminant that has been deposited on a plant surface. The term <math>kp</math> is a measure of the amount of contaminant lost to these physical processes over time. U.S. EPA (1990) cited Miller and Hoffman (1983) for the following equation used to estimate <math>kp</math>:</p> $kp = (\ln 2 / t_{1/2}) \cdot 365 \text{ days/yr}$ <p>where:</p> $t_{1/2} = \text{half-time (days)}$ <p>Miller and Hoffman (1983) report half-time values ranging from 2.8 to 34 days for a variety of contaminants on herbaceous vegetation. These half-time values result in <math>kp</math> values of 7.44 to 90.36 <math>\text{yr}^{-1}</math>. U.S. EPA (1993; 1994b) recommend a <math>kp</math> value of 18, based on a generic 14-day half-time, corresponding to physical processes only. The 14-day half-time is approximately the midpoint of the range (2.8 to 34 days) estimated by Miller and Hoffman (1983).</p> <p>Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) Calculation of <math>kp</math> does not consider chemical degradation processes. The addition of chemical degradation processes would decrease half-times and thereby increase <math>kp</math> values; plant concentration decreases as <math>kp</math> increases. Therefore, use of a <math>kp</math> value that does not consider chemical degradation processes is conservative.</li> <li>(2) The half-time values reported by Miller and Hoffman (1983) may not accurately represent the behavior of all COPCs on plants.</li> <li>(3) Based on this range (7.44 to 90.36), plant concentrations could range from about 1.8 times higher to about 5 times lower than the plant concentrations, based on a <math>kp</math> value of 18.</li> </ol> |

#### REFERENCES AND DISCUSSION

Baes, C.F., R.D. Sharp, A.L. Sjoreen, and R.W. Shor. 1984. *Review and Analysis of Parameters and Assessing Transport of Environmentally Released Radionuclides through Agriculture*. ORNL-5786. Oak Ridge National Laboratory. Oak Ridge, Tennessee. September.

This document proposed using the same empirical relationship developed by Chamberlain (1970) for other vegetation classes. Class-specific estimates of the empirical constant,  $\gamma$ , were developed by forcing an exponential regression equation through several points, including average and theoretical maximum estimates of  $Rp$  and  $Yp$ .

Belcher, G.D., and C.C. Travis. 1989. "Modeling Support for the RURA and Municipal Waste Combustion Projects: Final Report on Sensitivity and Uncertainty Analysis for the Terrestrial Food Chain Model." Interagency Agreement No. 1824-A020-A1, Office of Risk Analysis, Health and Safety Research Division, Oak Ridge National Laboratory. Oak Ridge, Tennessee. October.

This document recommends  $Tp$  values based on the average period between successive hay harvests and successive grazing.

Bidleman, T.F. 1988. "Atmospheric Processes." *Environmental Science and Technology*. Volume 22. Pages 361-367. November 4.

This document is cited by U.S. EPA (1994a) and NC DEHNR (1997) as the source of the equations for calculating  $F_v$ .

Chamberlain, A.C. 1970. "Interception and Retention of Radioactive Aerosols by Vegetation." *Atmospheric Environment*. 4:57 to 78.

Experimental studies of pasture grasses identified a correlation between initial  $Rp$  values and productivity (standing crop biomass [ $Yp$ ]):

$$\begin{aligned}Rp &= 1 - e^{-\gamma \times Yp} \\ \gamma &= \text{Empirical constant; range provided as 2.3 to 3.3} \\ Yp &= \text{Standing crop biomass (productivity) (kg DW/m}^2\text{)}\end{aligned}$$

Hoffman, F.O., K.M. Thiessen, M.L. Frank, and B.G. Blaylock. 1992. "Quantification of the Interception and Initial Retention of Radioactive Contaminants Deposited on Pasture Grass by Simulated Rain." *Atmospheric Environment*. Vol. 26A. 18:3313 to 3321.

This document developed values for a parameter ( $r$ ) that it termed "interception fraction," based on a study in which soluble gamma-emitting radionuclides and insoluble particles tagged with gamma-emitting radionuclides were deposited onto pasture grass (specifically, a combination of fescues, clover, and old field vegetation, including fescue) via simulated rain. The parameter,  $r$ , is defined as "the fraction of material in rain intercepted by vegetation and initially retained" or, essentially, the product of  $Rp$  and  $Fw$ , as defined by this guidance:

$$r = Rp \cdot Fw$$

Experimental  $r$  values obtained include the following:

- A range of 0.006 to 0.3 for anions (based on the soluble radionuclide iodide-131 [ $^{131}\text{I}$ ]); when calculating  $Rp$  values for anions, U.S. EPA (1994a) used the highest geometric mean  $r$  value (0.08) observed in the study.

## TABLE B-3-1

### PLANT CONCENTRATION DUE TO DIRECT DEPOSITION (TERRESTRIAL PLANT EQUATIONS)

(Page 9 of 10)

- A range of 0.1 to 0.6 for cations (based on the soluble radionuclide beryllium-7 [<sup>7</sup>Be]; when calculating *Rp* values for cations, U.S. EPA (1994a) used the highest geometric mean *r* value (0.28) observed in the study.
- A geometric range of values from 0.30 to 0.37 for insoluble polystyrene microspheres (IPM) ranging in diameter from 3 to 25 micrometers, labeled with cerium-141 [<sup>141</sup>Ce], [<sup>95</sup>Nb], and strontium-85 [<sup>85</sup>Sr]; when calculating *Rp* values for organics (other than three organics that ionize to anionic forms: 4-chloroaniline; n-nitrosodiphenylamine; and n-nitrosodi-n-propylamine, —see Appendix A-2), U.S. EPA (1994a) used the geometric mean *r* value for IPM with a diameter of 3 micrometers. However, no rationale for this selection was provided.

The authors concluded that, for the soluble <sup>131</sup>I anion, interception fraction *r* is an inverse function of rain amount, whereas for the soluble cation <sup>7</sup>Be and the IPMs, *r* depends more on biomass than on amount of rainfall. The authors also concluded that (1) the anionic <sup>131</sup>I is essentially removed with the water after the vegetation surface has become saturated, and (2) the cationic <sup>7</sup>Be and the IPMs are adsorbed to, or settle out on, the plant surface. This discrepancy between the behavior of the anionic and cationic species is consistent with a negative charge on the plant surface.

Miller, C.W. and F.O. Hoffman. 1983. "An Examination of the Environmental Half-Time for Radionuclides Deposited on Vegetation." *Health Physics*. 45 (3): 731 to 744.

This document is the source of the equation used to calculate *kp*:

$$\begin{aligned}kp &= (\ln 2 / t_{1/2}) \cdot 365 \text{ days/year} \\t_{1/2} &= \text{half-time (days)}\end{aligned}$$

The study reports half-time values ranging from 2.8 to 34 days for a variety of contaminants on herbaceous vegetation. These half-time values result in calculate *kp* values from 7.44 to 90.36 yr<sup>-1</sup>.

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

Shor, R.W., C.F. Baes, and R.D. Sharp. 1982. *Agricultural Production in the United States by County: A Compilation of Information from the 1974 Census of Agriculture for Use in Terrestrial Food-Chain Transport and Assessment Models*. Oak Ridge National Laboratory Publication. ORNL-5786.

This document is the source of the equation used to calculate *Yp*, as cited by U.S. EPA (1994b). Baes, Sharp, Sjoreen, and Shor (1984) also presents and discusses this equation.

TABLE B-3-2

**PLANT CONCENTRATION DUE TO AIR-TO-PLANT TRANSFER  
(TERRESTRIAL PLANT EQUATIONS)**

(Page 1 of 5)

**Description**

This equation calculates the COPC concentration in plants, resulting from uptake of vapor phase COPCs by plants through their foliage.

The limitations and uncertainty associated with calculating this value include the following:

- (1) The algorithm used to calculate values for the variable  $F_v$  assumes a default value for the parameter  $S_T$  (Whitby's average surface area of particulates [aerosols]) of background plus local sources, rather than an  $S_T$  value for urban sources. If a specific site is located in an urban area, the use of the latter  $S_T$  value may be more appropriate. The  $S_T$  value for urban sources is about one order of magnitude greater than that for background plus local sources and would result in a lower  $F_v$  value; however, the  $F_v$  value is likely to be only a few percent lower.

As highlighted by uncertainties described above,  $P_v$  is most significantly affected by the value calculated for  $B_v$ .

**Equation**

$$P_v = Q \cdot F_v \cdot 0.12 \cdot \frac{C_{yv} \cdot B_v}{\rho_a}$$

**For mercury modeling**

$$P_{v_{Mercury}} = (0.48Q_{TotalMercury}) \cdot F_{v_{Hg^{2+}}} \cdot 0.12 \cdot \frac{C_{yv} \cdot B_{v_{Hg^{2+}}}}{\rho_a}$$

In calculating  $P_v$  for mercury compounds,

$P_v(Mercury)$  is calculated as shown above using the

total mercury emission rate ( $Q$ ) measured at the stack and  $F_v$  for mercuric chloride ( $F_v = 0.85$ ). As presented below, the calculated  $P_v(Mercury)$  value is apportioned into the divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) forms based on a 78%  $Hg^{2+}$  and 22% MHg speciation split in plants (see Chapter 2).

$$P_v(Hg^{2+}) = 0.78 P_v(Mercury)$$

$$P_v(MHg) = 0.22 P_v(Mercury)$$

After calculating species specific  $P_v$  values, divalent and methyl mercury should continue to be modeled throughout Appendix B equations as individual COPCs.

**REFERENCES AND DISCUSSION**

Bacci E., D. Calamari, C. Gaggi, and M. Vighi. 1990. "Bioconcentration of Organic Chemical Vapors in Plant Leaves: Experimental Measurements and Correlation." *Environmental Science and Technology*. Volume 24. Number 6. Pages 885-889.

This is the source of the equation to adjust  $B_{vol}$ , based on volume/volume basis, to  $B_v$  on a mass/mass basis—see Bacci, Cerejeira, Gaggi, Chemello, Calamari, and Vighi (1992) below.

Bacci E., M. Cerejeira, C. Gaggi, G. Chemello, D. Calamari, and M. Vighi. 1992. "Chlorinated Dioxins: Volatilization from Soils and Bioconcentration in Plant Leaves." *Bulletin of Environmental Contamination and Toxicology*. Volume 48. Pages 401-408.

This is the source of the algorithm based on a study of 14 organic compounds, including 1,2,3,4-TCDD, used to calculate the air-to-plant biotransfer factor ( $B_v$ ):

$$\log B_{vol} = 1.065 \log K_{ow} - \log \left( \frac{H}{R \cdot T_a} \right) - 1.654$$

where:

|           |   |                                                                                      |
|-----------|---|--------------------------------------------------------------------------------------|
| $B_{vol}$ | = | Volumetric air-to-plant bio transfer factor ([ $\mu$ g/L wet leaf]/[ $\mu$ g/L air]) |
| $K_{ow}$  | = | Octanol-water partition coefficient (dimensionless)                                  |
| $H$       | = | Henry's Law Constant (atm-m <sup>3</sup> / mol)                                      |
| $R$       | = | Ideal gas constant, 8.2 x 10 <sup>-5</sup> atm-m <sup>3</sup> /mol-deg K             |
| $T_a$     | = | Ambient air temperature, 298.1 K (25°C)                                              |

This volumetric transfer factor can be transformed to a mass-based transfer factor by using the following equation (Bacci, Calamari, Gaggi, and Vighi 1990):

$$B_v = \frac{\rho_a \cdot B_{vol}}{(1 - f_{wc}) \cdot \rho_{forage}}$$

where:

|                 |   |                                                                                     |
|-----------------|---|-------------------------------------------------------------------------------------|
| $B_v$           | = | mass-based air-to-plant biotransfer factor ([ $\mu$ g/g DW plant]/[ $\mu$ g/g air]) |
| $B_{vol}$       | = | volumetric air-to-plant biotransfer factor ([ $\mu$ g/L wet leaf]/[ $\mu$ g/L air]) |
| $\rho_a$        | = | density of air, 1.19 g/L (Weast 1986)                                               |
| $\rho_{forage}$ | = | density of forage, 770 g/L (McCrady and Maggard, 1993)                              |
| $f_{wc}$        | = | fraction of forage that is water, 0.85 (McCrady and Maggard, 1993)                  |

Bidleman, T.F. 1988. "Atmospheric Processes." *Environmental Science and Technology*. Volume 22. Number 4. Pages 361-367.

## TABLE B-3-2

### PLANT CONCENTRATION DUE TO AIR-TO-PLANT TRANSFER (TERRESTRIAL PLANT EQUATIONS)

(Page 5 of 5)

This is the reference for the statement that the equation used to calculate the fraction of air concentration in vapor phase ( $F_v$ ) assumes that the variable  $c$  (the Junge constant) is constant for all chemicals; however, this reference notes that the value of  $c$  depends on the chemical (sorbate) molecular weight, the surface concentration for monolayer coverage, and the difference between the heat of desorption from the particle surface and the heat of vaporization of the liquid-phase sorbate.

This document is also cited by U.S. EPA (1994b) and NC DEHNR (1997) for calculating the variable  $F_v$ .

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

Taiz, L., and E. Geiger. 1991. *Plant Physiology*. Benjamin/Cammius Publishing Co. Redwood City, California. 559 pp.

U.S. EPA. 1990. *Interim Final Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Environmental Criteria and Assessment Office. Office of Research and Development. EPA-600-90-003. January.

This document is a source of air density values.

U.S. EPA. 1993. *Review Draft Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Office of Health and Environmental Assessment. Office of Research and Development. EPA-600-AP-93-003. November 10.

Based on attempts to model background concentrations of dioxin-like compounds in beef on the basis of known air concentrations, this document recommends reducing, by a factor of 10,  $B_v$  values calculated by using the Bacci, Cerejeira, Gaggi, Chemello, Calamari, and Vighi (1992) algorithm. The use of this factor “made predictions [of beef concentrations] come in line with observations.”

U.S. EPA. 1994a. *Estimating Exposure to Dioxin-Like Compounds. Volume II: Properties, Sources, Occurrence, and Background Exposures. Review Draft*. Office of Research and Development. Washington, DC. EPA/600/6-88/005Cb. June.

U.S. EPA. 1994b. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This is one of the source documents for Equation B-2-8. This document also presents a range (0.27 to 1) of  $F_v$  values for organic COPCs, based on the work of Bidleman (1988);  $F_v$  for all inorganics is set equal to zero.

| 0.12     | Dry weight to wet weight conversion factor | unitless                                    | <p align="center"><b>0.12</b></p> <p>U.S. EPA OSW recommends using the value of 0.12. This default value is based on the average rounded value from the range of 80 to 95 percent water content in herbaceous plants and nonwoody plant parts (Taiz et al. 1991).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The plant species considered in determining the default value may be different from plant varieties actually present at a site.</p>                                                                                                                                                                                                                                                                                                                                                                                                                    |
| $BCF_r$  | Plant-soil biotransfer factor              | unitless<br>[(mg/kg plant DW)/(mg/kg soil)] | <p align="center"><b>Varies (see Appendix C)</b></p> <p>This variable is COPC-specific. Discussion of this variable and COPC-specific values are presented in Appendix C.</p> <p>Uncertainties associated with this variable include the following:</p> <p>(1) Estimates of <math>BCF_r</math> for some inorganic COPCs, based on plant uptake response slope factors, may be more accurate than those based on BCF values from Baes, Sharp, Sjoeren, and Shor (1984).</p> <p>(2) U.S. EPA OSW recommends that uptake of organic COPCs from soil and transport of the COPCs to the aboveground portions of the plant be calculated on the basis of a regression equation developed in a study of the uptake of 29 organic compounds. This regression equation, developed by Travis and Arms (1988), may not accurately represent the behavior of all organic COPCs under site-specific conditions.</p> |

### TABLE B-3-3

#### PLANT CONCENTRATION DUE TO ROOT UPTAKE (TERRESTRIAL PLANT EQUATIONS)

(Page 3 of 3)

#### REFERENCES AND DISCUSSION

Baes, C.F., R.D. Sharp, A.L. Sjoeren, and R.W. Shor. 1984. *Review and Analysis of Parameters and Assessing Transport of Environmentally Released Radionuclides through Agriculture*. ORNL-5786. Oak Ridge National Laboratory. Oak Ridge, Tennessee. September.

Taiz, L., and E. Geiger. 1991. *Plant Physiology*. Benjamin/Cammius Publishing Co. Redwood City, California. 559 pp.

Travis, C.C. and A.D. Arms. 1988. "Bioconcentration of Organics in Beef, Milk, and Vegetation." *Environmental Science and Technology*. 22:271 to 274.

Based on paired soil and plant concentration data for 29 organic compounds, this document developed a regression equation relating soil-to-plant BCF to  $K_{ow}$ :

$$\log BCF_r = 1.588 - 0.578 \log K_{ow}$$

U.S. EPA. 1995. *Review Draft Development of Human Health-Based and Ecologically-Based Exit Criteria for the Hazardous Waste Identification Project*. Volumes I and II. Office of Solid Waste. March 3.

This document recommended using the BCFs,  $B_v$  and  $B_r$ , from Baes, Sharp, Sjoeren, and Shor (1984), for calculating the uptake of inorganics into vegetative growth (stems and leaves) and nonvegetative growth (fruits, seeds, and tubers), respectively.

Although most BCFs used in this document come from Baes, Sharp, Sjoeren, and Shor (1984), values for some inorganics were apparently obtained from plant uptake response slope factors. These uptake response slope factors were calculated from field data, such as metal methodologies, and references used to calculate the uptake response slope factors are not clearly identified.

## APPENDIX C

### MEDIA-TO-RECEPTOR *BCF*s

Appendix C provides recommended guidance for determining values for media-to-receptor bioconcentration factors (*BCF*s) based on values reported in the scientific literature, or estimated using physical and chemical properties of the compound. Guidance on use of *BCF* values in the screening level ecological risk assessment is provided in Chapter 5.

Section C-1.0 provides the general guidance recommended to select or estimate *BCF* values. Sections C-1.1 through C-1.7 further discuss determination of *BCF*s for specific media and receptors. References cited in Sections C-1.1 through C-1.7 are located following Section C-1.7.

For the compounds commonly identified in risk assessments for combustion facilities (identified in Chapter 2), *BCF* values have been determined following the guidance in Sections C-1.1 through C-1.7. *BCF* values for these limited number of compounds are included in this appendix in Tables C-1 through C-7 to facilitate the completion of screening ecological risk assessments. However, it is expected that additional compounds may require evaluation on a site specific basis, and in such cases, *BCF* values for these additional compounds could be determined following the same guidance (Sections C-1.1 through C-1.7) used in determination of the *BCF* values reported in this appendix. For reproducibility and to facilitate comparison of new data and values as they become available, all data reviewed in the selection of the *BCF* values provided at the end of this appendix are also included in Tables C-1 through C-7. References cited in Tables C-1 through C-7 (Media-to-Receptor *BCF* Values) are located following Table C-7.

For additional discussion on some of the references and equations cited in Sections C-1.1 through C-1.7, the reader is recommended to review the Human Health Risk Assessment Protocol (HHRAP) (U.S. EPA 1998) (see Appendix A-3), and the source documents cited in the reference section of this appendix.

#### C-1.0 GENERAL GUIDANCE

This section summarizes the recommended general guidance for determining compound-specific *BCF* values (media-to-receptors) provided in Tables C-1 through C-7. As a preference, *BCF* values were selected from empirical field and/or laboratory data generated from reviewed studies that are published in the scientific literature. Information used from these studies included calculated *BCF* values, as well as, collocated media and organism concentration data from which *BCF* values could be calculated. If two or more *BCF* values, or two or more sets of collocated data, were available in the published scientific literature, the geometric mean of the values was used.

Field-derived *BCF* values were considered more indicative of the level of bioconcentration occurring in the natural environment than laboratory-derived values. Therefore, when available and appropriate, field-derived *BCF* values were given priority over laboratory-derived values. In some cases, confidence in the methods used to determine or report field-derived *BCF* values was less than for the laboratory-derived values. In those cases, the laboratory-derived values were used for the recommended *BCF* values.

When neither field or laboratory data were available for a specific compound, data from a potential surrogate compound were evaluated. The appropriateness of the surrogate was determined by comparing the structures of the two compounds. Where an appropriate surrogate was not identified, a regression equation based on the compound's log  $K_{ow}$  value was used to calculate the recommended *BCF* value.

With the exception of the air-to-plant biotransfer factors (*B<sub>v</sub>*), recommended *BCF* values provided in the tables at the end of this appendix are based on wet tissue weight and dry media weight (except for water). As necessary, reported values were converted to these units using the referenced tissue or media wet weight percentages. The conversion factors, equations, and references for these conversions are discussed in Sections C-1.1 through C-1.7 where appropriate, and are presented at the end of each table (Tables C-1 through C-7).

### C-1.1 SOIL-TO-SOIL INVERTEBRATE BIOCONCENTRATION FACTORS

Soil-to-soil invertebrate *BCF* values (see Table C-1) were developed mainly from data for earthworms. Measured experimental results were primarily in the form of ratios of compound concentrations in a earthworm and the compound concentrations in the soil in which the earthworm was exposed. As necessary, values were converted to wet tissue and dry media weight assuming a moisture content (by mass) of 83.3 percent for earthworms and 20 percent for soil (Pietz et al. 1984).

Organics For organic compounds with no field or laboratory data available, recommended *BCF* values were estimated using the following regression equation:

$$\log BCF = 0.819 \log K_{ow} - 1.146 \quad \text{Equation C-1-1}$$

- Southworth, G.R., J.J. Beauchamp, and P.K. Schmieder. 1978. "Bioaccumulation Potential of Polycyclic Aromatic Hydrocarbons in *Daphnia Pulex*." *Water Research*. Volume 12. Pages 973-977.

Inorganics For inorganic compounds with no field or laboratory data available, the recommended *BCF* value is equal to the arithmetic average of the available *BCF* values for other inorganics as specified in Table C-1.

### C-1.2 SOIL-TO-PLANT AND SEDIMENT-TO-PLANT BIOCONCENTRATION FACTORS

Soil-to-plant *BCF* values (see Table C-2) account for plant uptake of compounds from soil. Data for a variety of plants and food crops were used to determine recommended *BCF* values.

Organics For all organics (including PCDDs and PCDFs) with no available field or laboratory data, the following regression equation was used to calculate recommended values:

$$\log BCF = 1.588 - 0.578 \log K_{ow} \quad \text{Equation C-1-2}$$

- Travis, C.C. and A.D. Arms. 1988. "Bioconcentration of Organics in Beef, Milk, and Vegetation." *Environmental Science and Technology*. 22:271-274.

Inorganics For most metals, *BCF* values were based on empirical data reported in the following:

- Baes, C.F., R.D. Sharp, A.L. Sjoreen, and R.W. Shor. 1984. "Review and Analysis of Parameters and Assessing Transport of Environmentally Released Radionuclides Through Agriculture." Oak Ridge National Laboratory, Oak Ridge, Tennessee.

The scientific literature also was searched to identify studies. Although U.S. EPA (1995a) provides values for certain metals calculated on the basis of plant uptake response slope factors, it is unclear how the *BCF*

values were calculated or which sources or references were used. Therefore, values reported in U.S. EPA (1995a) were not used.

### C-1.3 WATER-TO-AQUATIC INVERTEBRATE BIOCONCENTRATION FACTORS

Experimental data for crustaceans, aquatic insects, bivalves, and other aquatic invertebrates were used to determine recommended *BCF* values for water-to-aquatic invertebrate (see Table C-3). Both marine and freshwater exposures were reviewed. As necessary, available results were converted to wet tissue weight assuming that invertebrate moisture content (by mass) is 83.3 percent (Pietz et al. 1984).

Organics Reported field values for organic compounds were assumed to be total compound concentrations in water and, therefore, were converted to dissolved compound concentrations in water using the following equation from U.S. EPA (1995b):

$$BCF \text{ (dissolved)} = (BCF \text{ (total)} / f_{fd}) - 1 \quad \text{Equation C-1-3}$$

where

*BCF* (dissolved) = *BCF* based on dissolved concentration of compound in water

*BCF* (total) = *BCF* based on the field derived data for total concentration of compound in water

$f_{fd}$  = Fraction of compound that is freely dissolved in the water

and,

$f_{fd}$  =  $1 / [1 + ((DOC \times K_{ow}) / 10) + (POC \times K_{ow})]$

*DOC* = Dissolved organic carbon, kilograms of organic carbon / liter of water ( $2.0 \times 10^{-6}$  Kg/L)

$K_{ow}$  = Octanol-water partition coefficient of the compound, as reported in U.S. EPA (1994a)

*POC* = Particulate organic carbon, kilograms of organic carbon / liter of water ( $7.5 \times 10^{-9}$  Kg/L)

Laboratory data were assumed to be based on dissolved compound concentrations.

For organic compounds with no field or laboratory data available, *BCF* values were determined from surrogate compounds or calculated using the following regression equation:

$$\log BCF = 0.819 \times \log K_{ow} - 1.146 \quad \text{Equation C-1-4}$$

- Southworth, G.R., J.J. Beauchamp, and P.K. Schmieder. 1978. "Bioaccumulation Potential of Polycyclic Aromatic Hydrocarbons in *Daphnia Pulex*." *Water Research*. Volume 12. Pages 973-977.

Inorganics For inorganic compounds with no field or laboratory data available, the recommended *BCF* values were estimated as the arithmetic average of the available *BCF* values for other inorganics, as specified in Table C-3.

**C-1.4 WATER-TO-ALGAE BIOCONCENTRATION FACTORS**

Experimental data for both marine and freshwater algal species were reviewed. As necessary, available results were converted to wet tissue weight assuming that algae moisture content (by mass) is 65.7 percent (Isensee et al. 1973).

Organics For organic compounds with no field or laboratory data available, BCF values were calculated using the following regression equation:

$$\log BCF = 0.819 \times \log K_{ow} - 1.146 \quad \text{Equation C-1-5}$$

- Southworth, G.R., J.J. Beauchamp, and P.K. Schmieder. 1978. "Bioaccumulation Potential of Polycyclic Aromatic Hydrocarbons in *Daphnia Pulex*." *Water Research*. Volume 12. Pages 973-977.

Inorganics For inorganics, available field or laboratory data were evaluated for each compound.

**C-1.5 WATER-TO-FISH BIOCONCENTRATION FACTORS**

Experimental data for a variety of marine and freshwater fish were used to determine recommended BCF values (see Table C-5). As necessary, values were converted to wet tissue weight assuming that fish moisture content (by mass) is 80.0 percent (Holcomb et al. 1976).

For both organic and inorganic compounds, reported field values were considered bioaccumulation factors (BAFs) based on contributions of compounds from food sources as well as media. Therefore, field values were converted to BCFs based on the trophic level of the test organism using the following equation:

$$BCF = (BAF_{TLn} / FCM_{TLn}) - 1 \quad \text{Equation C-1-6}$$

where

|             |   |                                                                                           |
|-------------|---|-------------------------------------------------------------------------------------------|
| $BAF_{TLn}$ | = | The reported field bioaccumulation factor for the trophic level "n" of the study species. |
| $FCM_{TLn}$ | = | The food chain multiplier for the trophic level "n" of the study species.                 |

Organics Reported field values for organic compounds were assumed to be total compound concentrations in water and, therefore, were converted to dissolved compound concentrations in water using the following equation from U.S. EPA (1995b):

$$BAF \text{ (dissolved)} = (BAF \text{ (total)} / f_{fd}) - 1 \quad \text{Equation C-1-7}$$

where

|                           |   |                                                                                  |
|---------------------------|---|----------------------------------------------------------------------------------|
| $BAF \text{ (dissolved)}$ | = | BAF based on dissolved concentration of compound in water                        |
| $BAF \text{ (total)}$     | = | BAF based on the field derived data for total concentration of compound in water |
| $f_{fd}$                  | = | Fraction of compound that is freely dissolved in the water                       |

and,

|          |   |                                                                                             |
|----------|---|---------------------------------------------------------------------------------------------|
| $f_{fd}$ | = | $1 / [1 + ((DOC \times K_{ow}) / 10) + (POC \times K_{ow})]$                                |
| $DOC$    | = | Dissolved organic carbon, Kg of organic carbon / L of water ( $2.0 \times 10^{-06}$ Kg/L)   |
| $K_{ow}$ | = | Octanol-water partition coefficient of the compound, as reported in U.S. EPA (1994a)        |
| $POC$    | = | Particulate organic carbon, Kg of organic carbon / L of water ( $7.5 \times 10^{-09}$ Kg/L) |

Laboratory data were assumed to be based on dissolved compound concentrations.

For organics for which no field or laboratory data were available, the following regression equation was used to calculate the recommended *BCF* values:

$$\log BCF = 0.91 \times \log K_{ow} - 1.975 \times \log (6.8E-07 \times K_{ow} + 1.0) - 0.786 \quad \text{Equation C-1-8}$$

- Bintein, S., J. Devillers, and W. Karcher. 1993. "Nonlinear Dependence of Fish Bioconcentrations on n-Octanol/Water Partition Coefficients." *SAR and QSAR in Environmental Research*. Vol. 1. Pages 29-39.

*Inorganics* For inorganic compounds with no available field or laboratory data, the recommended *BCF* values were estimated as the arithmetic average of the available *BCF* values reported for other inorganics.

#### C-1.6 SEDIMENT-TO-BENTHIC INVERTEBRATE BIOCONCENTRATION FACTORS

Experimental data for a variety of benthic infauna, worms, insects, and other invertebrates were used to determine the recommended *BCF* values for sediment-to-benthic invertebrate (see Table C-6). As necessary, values were converted to wet tissue weight assuming that benthic invertebrate moisture content (by mass) is 83.3 percent (Pietz et al. 1984).

*Organics* For organic compound (including PCDDs and PCDFs) with no available field or laboratory data, the recommended *BCF* values were determined using the following regression equation:

$$\log BCF = 0.819 \times \log K_{ow} - 1.146 \quad \text{Equation C-1-9}$$

- Southworth, G.R., J.J. Beauchamp, and P.K. Schmieder. 1978. "Bioaccumulation Potential of Polycyclic Aromatic Hydrocarbons in *Daphnia Pulex*." *Water Research*. Volume 12. Pages 973-977.

*Inorganics* For inorganic compound with no available field or laboratory data, the recommended *BCF* values were estimated as the arithmetic average of the available *BCF* values for other inorganics.

#### C-1.7 AIR-TO-PLANT BIOCONCENTRATION FACTORS

The air-to-plant bioconcentration (*Bv*) factor (see Table C-7) is defined as the ratio of compound concentrations in exposed aboveground plant parts to the compound concentration in air. *Bv* values in Table C-7 are reported on dry-weight basis since the plant concentration equations (see Chapter 3) already include a dry-weight to wet-weight conversion factor.

Organics For organics (excluding PCDDs and PCDFs), the air-to-plant bioconcentration factor was calculated using regression equations derived for azalea leaves in the following documents:

- Bacci E., D. Calamari, C. Gaggi, and M. Vighi. 1990. "Bioconcentration of Organic Chemical Vapors in Plant Leaves: Experimental Measurements and Correlation." *Environmental Science and Technology*. Volume 24. Number 6. Pages 885-889.
- Bacci E., M. Cerejeira, C. Gaggi, G. Chemello, D. Calamari, and M. Vighi. 1992. "Chlorinated Dioxins: Volatilization from Soils and Bioconcentration in Plant Leaves." *Bulletin of Environmental Contamination and Toxicology*. Volume 48. Pages 401-408.

Bacci et al. (1992) developed a regression equation using empirical data collected for the uptake of 1,2,3,4-TCDD in azalea leaves and data obtained from Bacci et al. (1990). The bioconcentration factor obtained was included in a series of 14 different organic compounds to develop a correlation equation with  $K_{ow}$  and  $H$  (defined below). Bacci et al. (1992) derived the following equations:

$$\log B_{vol} = 1.065 \log K_{ow} - \log \left( \frac{H}{RT} \right) - 1.654 \quad (r = 0.957) \quad \text{Equation C-1-10}$$

$$Bv = \frac{\rho_{air} \cdot B_{vol}}{(1 - f_{water}) \cdot \rho_{forage}} \quad \text{Equation C-1-11}$$

where

|                 |   |                                                                    |
|-----------------|---|--------------------------------------------------------------------|
| $B_{vol}$       | = | Volumetric air-to-plant biotransfer factor (fresh-weight basis)    |
| $Bv$            | = | Air-to-plant biotransfer factor (dry-weight basis)                 |
| $\rho_{air}$    | = | 1.19 g/L (Weast 1986)                                              |
| $\rho_{forage}$ | = | 770 g/L (Macrady and Maggard 1993)                                 |
| $f_{water}$     | = | 0.85 (fraction of forage that is water—Macrady and Maggard [1993]) |
| $H$             | = | Henry's Law constant (atm-m <sup>3</sup> /mole)                    |
| $R$             | = | Universal gas constant (atm-m <sup>3</sup> /mole °K)               |
| $T$             | = | Temperature (25 °C, 298 °K)                                        |

Equations C-1-10 and C-1-11 are used to calculate  $Bv$  values (see Table C-7) using the recommended values of  $H$  and  $K_{ow}$  provided in Appendix A at a temperature ( $T$ ) of 25 °C or 298.1 K. The following uncertainty should be noted with use of  $Bv$  values calculated using these equations:

- For organics (except PCDDs and PCDFs), U.S. EPA (1993) recommended that  $B_v$  values be reduced by a factor of 10 before use. This was based on the work conducted by U.S. EPA (1993) for U.S. EPA (1994b) as an interim correction factor. Welsch-Pausch, McLachlan, and Umlauf (1995) conducted experiments to determine concentrations of PCDDs and PCDFs in air and resulting biotransfer to welsh ray grass. This was documented in the following:
  - Welsch-Pausch, K.M. McLachlan, and G. Umlauf. 1995. "Determination of the Principal Pathways of Polychlorinated Dibenzo-p-dioxins and Dibenzofurans to *Lolium Multiflorum* (Welsh Ray Grass)". *Environmental Science and Technology*. 29: 1090-1098.

A follow-up study based on Welsch-Pausch, McLachlan, and Umlauf (1995) experiments was conducted by Lorber (1995) (see discussion below for PCDDs and PCDFs). In a following publication, Lorber (1997) concluded that the Bacci factor reduced by a factor of 100 was close in line with observations made by him through various studies, including the Welsch-Pausch, McLachlan, and Umlauf (1995) experiments. Therefore, this guidance recommends that  $B_v$  values be calculated using the Bacci, Cerejeira, Gaggi, Chemello, Calamari, and Vighi (1992) correlation equations and then reduced by a factor of 100 for all organics, excluding PCDDs and PCDFs.

**PCDDs and PCDFs** For PCDDs and PCDFs,  $B_v$  values, on a dry weight basis, were obtained from the following:

- Lorber, M., and P. Pinsky. 1999. "An Evaluation of Three Empirical Air-to-Leaf Models for Polychlorinated Dibenzo-p-Dioxins and Dibenzofurans." National Center for Environmental Assessment (NCEA). U. S. EPA, 401 M St. SW, Washington, DC. *Accepted for Publication in Chemosphere*.

U.S. EPA (1993) stated that, for dioxin-like compounds, the use of the Bacci, Cerejeira, Gaggi, Chemello, Calamari, and Vighi (1992) equations may overpredict  $B_v$  values by a factor of 40. This was because the Bacci, Calamari, Gaggi, and Vighi (1990) and Bacci, Cerejeira, Gaggi, Chemello, Calamari, and Vighi (1992) experiments did not take photodegradation effects into account. Therefore,  $B_v$  values calculated using Equations C-10 and C-11 were recommended to be reduced by a factor of 40 for dioxin-like compounds.

However, according to Lorber (1995), the Bacci algorithm divided by 40 may not be appropriate because (1) the physical and chemical properties of dioxin congeners are generally outside the range of the 14 organic compounds used by Bacci, Calamari, Gaggi, and Vighi (1990), and (2) the factor of 40 derived from one experiment on 2,3,7,8-TCDD may not apply to all dioxin congeners.

Welsch-Pausch, McLachlan, and Umlauf (1995) conducted experiments to obtain data on uptake of PCDDs and PCDFs from air to *Lolium Multiflorum* (Welsh Ray grass). The data includes grass concentrations and air concentrations for dioxin-congener groups, but not the individual congeners. Lorber (1995) used data from Welsch-Pausch, McLachlan, and Umlauf (1995) to develop an air-to-leaf transfer factor for each dioxin-congener group.  $B_v$  values developed by Lorber (1995) were about an order of magnitude less than values that would have been calculated using the Bacci, Calamari, Gaggi, and Vighi (1990; 1992) correlation equations. Lorber (1995) speculated that this difference could be attributed to several factors including experimental design, climate, and lipid content of plant species used.

Lorber (1999) conducted an evaluation of three empirical air-to-leaf models for estimating grass concentrations of PCDDs and PCDFs from air concentrations of these compounds described and tested against field data. *Bv* values recommended for PCDDs and PCDFs in this guidance were obtained from the experimentally derived values of Lorber (1999).

**Metals** For metals, no literature sources were available for *Bv* values. U.S. EPA (1995a) quoted from the following document, that metals were assumed not to experience air to leaf transfer:

- Belcher, G.D., and C.C. Travis. 1989. "Modeling Support for the RURA and Municipal Waste Combustion Projects: Final Report on Sensitivity and Uncertainty Analysis for the Terrestrial Food Chain Model." Interagency Agreement No. 1824-A020-A1. Office of Risk Analysis, Health and Safety Research Division. Oak Ridge National Laboratory. Oak Ridge, Tennessee. October.

Consistent with the above references, *Bv* values for metals (excluding elemental mercury) were assumed to be zero (see Table C-7).

**Mercuric Compounds** Mercury emissions are assumed to consist of both the elemental and divalent forms. However, only small amounts of elemental mercury is assumed to be deposited (see Chapter 2). Elemental mercury either dissipates into the global cycle or is converted to the divalent form. Methyl mercury is assumed not to exist in the stack emissions or in the air phase. Consistent with various discussions in Chapter 2 concerning mercury, (1) elemental mercury reaching or depositing onto the plant surfaces is negligible, and (2) biotransfer of methyl mercury from air is zero. This is based on assumptions made regarding speciation and fate and transport of mercury from stack emissions. Therefore, the *Bv* value for (1) elemental mercury was assumed to be zero, and (2) methyl mercury was assumed not to be applicable. *Bv* values for mercuric chloride (dry weight basis) were obtained from U.S. EPA (1997).

It should be noted that uptake of mercury from air into the aboveground plant tissue is primarily in the divalent form. A part of the divalent form of mercury is assumed to be converted to the methyl mercury form once in the plant tissue.

|---------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|-------------------------|--------------------------------------------------------------|
| <b>Dioxins and Furans</b>                                                                                                                               |                                                       |                         |                                                              |
| Compound: 2,3,7,8-tetrachlorodibenzo-p-dioxin                                                                                                           |                                                       |                         | Recommended BCF Value: 1.59                                  |
| The BCF was calculated using the geometric mean of 5 laboratory values for 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) as follows:                       |                                                       |                         |                                                              |
| 14.5                                                                                                                                                    | Martinucci, Crespi, Omodeo, Osella, and Traldi (1983) | 20-day exposure         | Not specified                                                |
| 9.41    0.64<br>0.68    0.17                                                                                                                            | Reinecke and Nash (1984)                              | 20-day exposure         | <i>Allolobaphora caliginosa</i><br><i>Lumbricus rubellus</i> |
| Compound: 1,2,3,7,8-pentachlorodibenzo-p-dioxin                                                                                                         |                                                       |                         | Recommended Value: 1.46                                      |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.92 = 1.46$   |                                                       |                         |                                                              |
| Compound: 1,2,3,4,7,8-hexachlorodibenzo-p-dioxin                                                                                                        |                                                       |                         | Recommended Value: 0.49                                      |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.31 = 0.49$   |                                                       |                         |                                                              |
| Compound: 1,2,3,6,7,8-hexachlorodibenzo-p-dioxin                                                                                                        |                                                       |                         | Recommended Value: 0.19                                      |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.12 = 0.19$   |                                                       |                         |                                                              |
| Compound: 1,2,3,7,8,9-hexachlorodibenzo-p-dioxin                                                                                                        |                                                       |                         | Recommended Value: 0.22                                      |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.14 = 0.22$   |                                                       |                         |                                                              |
| Compound: 1,2,3,4,6,7,8,-heptachlorodibenzo-p-dioxin                                                                                                    |                                                       |                         | Recommended Value: 0.081                                     |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.051 = 0.081$ |                                                       |                         |                                                              |
| Compound: Octachlorodibenzo-p-dioxin                                                                                                                    |                                                       |                         | Recommended Value: 0.019                                     |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.012 = 0.019$ |                                                       |                         |                                                              |
| Compound: 2,3,7,8-tetrachlorodibenzofuran                                                                                                               |                                                       |                         | Recommended BCF Value: 1.27                                  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.80 = 1.27$   |                                                       |                         |                                                              |
| Compound: 1,2,3,7,8-pentachlorodibenzofuran                                                                                                             |                                                       |                         | Recommended BCF Value: 0.32                                  |

|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|-------------------------|------------------------------|
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.22 = 0.32$                                                                                                         |                                       |                         |                              |
| Compound:                                                                                                                                                                                                                                                     | 2,3,4,7,8-pentachlorodibenzofuran     |                         | Recommended BCF Value: 2.54  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 1.6 = 2.54$                                                                                                          |                                       |                         |                              |
| Compound:                                                                                                                                                                                                                                                     | 1,2,3,4,7,8-hexachlorodibenzofuran    |                         | Recommended BCF Value: 0.121 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.076 = 0.121$                                                                                                       |                                       |                         |                              |
| Compound:                                                                                                                                                                                                                                                     | 1,2,3,6,7,8-hexachlorodibenzofuran    |                         | Recommended BCF Value: 0.30  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.19 = 0.30$                                                                                                         |                                       |                         |                              |
| Compound:                                                                                                                                                                                                                                                     | 2,3,4,6,7,8-hexachlorodibenzofuran    |                         | Recommended BCF Value: 1.07  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.67 = 1.07$                                                                                                         |                                       |                         |                              |
| Compound:                                                                                                                                                                                                                                                     | 1,2,3,7,8,9-hexachlorodibenzofuran    |                         | Recommended BCF Value: 1.00  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.63 = 1.00$                                                                                                         |                                       |                         |                              |
| Compound:                                                                                                                                                                                                                                                     | 1,2,3,4,6,7,8-heptachlorodibenzofuran |                         | Recommended BCF Value: 0.017 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.011 = 0.017$                                                                                                       |                                       |                         |                              |
| Compound:                                                                                                                                                                                                                                                     | 1,2,3,4,7,8,9-heptachlorodibenzofuran |                         | Recommended BCF Value: 0.62  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.39 = 0.62$                                                                                                         |                                       |                         |                              |
| Compound:                                                                                                                                                                                                                                                     | Octochlorodibenzofuran                |                         | Recommended BCF Value: 0.025 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1.59 \times 0.016 = 0.025$                                                                                                       |                                       |                         |                              |
| <b>Polynuclear Aromatic Hydrocarbons (PAHs)</b>                                                                                                                                                                                                               |                                       |                         |                              |
| Compound:                                                                                                                                                                                                                                                     | Benzo(a)pyrene                        |                         | Recommended BCF Value: 0.07  |
| The BCF was calculated using the geometric mean of 6 laboratory values for benzo(a)pyrene. The values reported in Rhett, Simmers, and Lee (1988) were converted to earthworm wet weight over soil dry weight using a conversion factor of 5.99 <sup>a</sup> . |                                       |                         |                              |

| Compound: 1,3-Dinitrobenzene                                                                                                                                                                                                                                                                                                         |            |                         | Recommended BCF Value: 1.19      |
| No empirical data were available for 1,3-dinitrobenzene or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation:<br>$\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 1.491$ (U.S. EPA 1994b).         |            |                         |                                  |
| Compound: 2,4-Dinitrotoluene                                                                                                                                                                                                                                                                                                         |            |                         | Recommended BCF Value: 3.08      |
| No empirical data were available for 2,4-dinitrotoluene or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation:<br>$\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 1.996$ (U.S. EPA 1994b).         |            |                         |                                  |
| Compound: 2,6-Dinitrotoluene                                                                                                                                                                                                                                                                                                         |            |                         | Recommended BCF Value: 2.50      |
| No empirical data were available for 2,6-dinitrotoluene or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation:<br>$\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 1.886$ (U.S. EPA 1994b).         |            |                         |                                  |
| Compound: Nitrobenzene                                                                                                                                                                                                                                                                                                               |            |                         | Recommended BCF Value: 2.26      |
| No empirical data were available for nitrobenzene or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation:<br>$\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 1.833$ (U.S. EPA 1994b).               |            |                         |                                  |
| Compound: Pentachloronitrobenzene                                                                                                                                                                                                                                                                                                    |            |                         | Recommended BCF Value: 451       |
| No empirical data were available for pentachloronitrobenzene or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation:<br>$\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 4.640$ (U.S. EPA 1994b).    |            |                         |                                  |
| <b>Phthalate Esters</b>                                                                                                                                                                                                                                                                                                              |            |                         |                                  |
| Compound: Bis(2-ethylhexyl)phthalate                                                                                                                                                                                                                                                                                                 |            |                         | Recommended BCF Value: 1,309     |
| No empirical data were available for bis(2-ethylhexyl)phthalate or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation:<br>$\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 5.205$ (U.S. EPA 1994b). |            |                         |                                  |
| Compound: Di(n)octyl phthalate                                                                                                                                                                                                                                                                                                       |            |                         | Recommended BCF Value: 3,128,023 |
| No empirical data were available for di(n)octyl phthalate or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation:<br>$\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 9.330$ (U.S. EPA 1994b).       |            |                         |                                  |

| <b>Volatile Organic Compounds</b>                                                                                                                                                                                                                                                                                                                                                   |            |                         |                             |
| Compound: Acetone                                                                                                                                                                                                                                                                                                                                                                   |            |                         | Recommended BCF Value: 0.05 |
| No empirical data were available for acetone or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation: $\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder (1978), where $\log K_{ow} = -0.222$ (Karickhoff and Long 1995).                                                          |            |                         |                             |
| Compound: Acrylonitrile                                                                                                                                                                                                                                                                                                                                                             |            |                         | Recommended BCF Value: 0.11 |
| No empirical data were available for acrylonitrile or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation: $\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 0.250$ (Karickhoff and Long 1995).                                                      |            |                         |                             |
| Compound: Chloroform                                                                                                                                                                                                                                                                                                                                                                |            |                         | Recommended BCF Value: 2.82 |
| No empirical data were available for chloroform or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation: $\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 1.949$ (U.S. EPA 1994b).                                                                   |            |                         |                             |
| Compound: Crotonaldehyde                                                                                                                                                                                                                                                                                                                                                            |            |                         | Recommended BCF Value: 0.20 |
| No empirical data were available for crotonaldehyde or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation: $\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 0.55$ (Based on equations developed by Hansch and Leo 1979, calculated in NRC (1981)). |            |                         |                             |
| Compound: 1,4-Dioxane                                                                                                                                                                                                                                                                                                                                                               |            |                         | Recommended BCF Value: 0.04 |
| No empirical data were available for 1,4-dioxane or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation: $\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = -0.268$ (U.S. EPA 1995a).                                                                 |            |                         |                             |
| Compound: Formaldehyde                                                                                                                                                                                                                                                                                                                                                              |            |                         | Recommended BCF Value: 0.14 |
| No empirical data were available for formaldehyde or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation: $\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 0.342$ (U.S. EPA 1995a).                                                                 |            |                         |                             |
| Compound: Vinyl chloride                                                                                                                                                                                                                                                                                                                                                            |            |                         | Recommended BCF Value: 0.62 |
| No empirical data were available for vinyl chloride or for a structurally-similar surrogate compound. The BCF was calculated using the following regression equation: $\log \text{BCF} = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 1.146$ (U.S. EPA 1994b).                                                               |            |                         |                             |

| Compound: Methyl mercury Recommended BCF Value: 8.50                                                                                                                                                                                                                                                                     |                                     |                                                                                                                                                                                     |                                                                        |
| The BCF was calculated using the geometric mean of 3 laboratory values as presented below. The values reported in Beyer, Cromartie, and Moment (1985) were earthworm wet weight over soil wet weight with 60 percent soil moisture. The soil weight was converted to dry weight to result in the values presented below: |                                     |                                                                                                                                                                                     |                                                                        |
| 8.25<br>8.31<br>8.95                                                                                                                                                                                                                                                                                                     | Beyer, Cromartie, and Moment (1985) | 6 to 12-week exposure                                                                                                                                                               | <i>Eisenia foetida</i>                                                 |

| 1.28                                                                                                                                                                                                                                                                 | Van Hook (1974)                | Chronic exposure        | <i>Alabophera</i> sp.<br><i>Lumbricus</i> sp.<br><i>Octolasion</i> sp. |

Notes:

- (a) The reported values are presented as the amount of COPC in invertebrate tissue divided by the amount of COPC in the soil. If the values reported in the studies were presented as dry tissue weight over dry soil weight, they were converted to wet weight over dry weight by dividing the concentration in dry earthworm tissue weight by 5.99. This conversion factor assumes an earthworm's total weight is 83.3 percent moisture (Pietz et al. 1984).

The conversion factor was calculated as follows:

$$\text{Conversion factor} = \frac{1.0 \text{ gram (g) earthworm total weight}}{1.0 \text{ g earthworm total weight} - 0.833 \text{ g earthworm wet weight}}$$

TABLE C-2

**SOIL-TO-PLANT AND SEDIMENT-TO- PLANT BIOCONCENTRATION FACTORS**  
**(mg COPC/kg dry tissue) / (mg COPC/kg dry soil or sediment)**

| <b>Dioxins and Furans</b>                                                                                                                               |                                   |                          |                               |
| Compound: 2,3,7,8-Tetrachlorodibenzo(p)dioxin (2,3,7,8-TCDD)                                                                                            |                                   |                          | Recommended BCF Value: 1,560  |
| The BCF value was calculated using the geometric mean of 2 values from data reported for 2,3,7,8-tetrachlorodibenzo(p)dioxin (2,3,7,8-TCDD).            |                                   |                          |                               |
| 1,762<br>1,381                                                                                                                                          | Yockim, Isensee, and Jones (1978) | 32-day exposure duration | Daphnid; <i>Heliosoma</i> sp. |
| Compound: 1,2,3,7,8-Pentachlorodibenzo(p)dioxin (1,2,3,7,8-PeCDD)                                                                                       |                                   |                          | Recommended BCF Value: 1,435  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1,560 \times 0.92 = 1,435$ |                                   |                          |                               |
| Compound: 1,2,3,4,7,8-Hexachlorodibenzo(p)dioxin (1,2,3,4,7,8-HxCDD)                                                                                    |                                   |                          | Recommended BCF Value: 483.6  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1,560 \times 0.31 = 483.6$ |                                   |                          |                               |
| Compound: 1,2,3,6,7,8-Hexachlorodibenzo(p)dioxin (1,2,3,6,7,8-HxCDD)                                                                                    |                                   |                          | Recommended BCF Value: 187.2  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1,560 \times 0.12 = 187.2$ |                                   |                          |                               |
| Compound: 1,2,3,7,8,9-Hexachlorodibenzo(p)dioxin (1,2,3,7,8,9-HxCDD)                                                                                    |                                   |                          | Recommended BCF Value: 218.4  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1,560 \times 0.14 = 218.4$ |                                   |                          |                               |
| Compound: 1,2,3,4,6,7,8-Heptachlorodibenzo(p)dioxin (1,2,3,4,6,7,8-HpCDD)                                                                               |                                   |                          | Recommended BCF Value: 79.6   |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1,560 \times 0.051 = 79.6$ |                                   |                          |                               |
| Compound: Octachlorodibenzo(p)dioxin (OCDD)                                                                                                             |                                   |                          | Recommended BCF Value: 18.7   |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1,560 \times 0.012 = 18.7$ |                                   |                          |                               |
| Compound: 2,3,7,8-Tetrachlorodibenzofuran (2,3,7,8-TCDF)                                                                                                |                                   |                          | Recommended BCF Value: 1248   |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1,560 \times 0.80 = 1248$  |                                   |                          |                               |
| Compound: 1,2,3,7,8-Pentachlorodibenzofuran (1,2,3,7,8-PeCDF)                                                                                           |                                   |                          | Recommended BCF Value: 343.2  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 1,560 \times 0.22 = 343.2$ |                                   |                          |                               |
| Compound: 2,3,4,7,8-Pentachlorodibenzofuran (2,3,4,7,8-PeCDF)                                                                                           |                                   |                          | Recommended BCF Value: 2,496  |

| Laboratory data were not available for this constituent. The recommended BCF is the arithmetic mean of the recommended values for 14 inorganics with laboratory data available (antimony, arsenic, barium, beryllium, cadmium, chromium, copper, lead, mercury, nickel, selenium, silver, thallium, and zinc). |                                            |                                                                                                                                                                                                                        |                                  |
| Compound:      Lead                                                                                                                                                                                                                                                                                            |                                            |                                                                                                                                                                                                                        | Recommended BCF Value: 5,059     |
| The BCF value was calculated using the geometric mean of 6 field values as follows:                                                                                                                                                                                                                            |                                            |                                                                                                                                                                                                                        |                                  |

| 519<br>315                   | 2,615<br>184 | Phillips (1976)                            | 35-day exposure duration | <i>Mytilus edulis</i> |
| 85                           |              | Pringle, Hissong, Katz, and Mulawka (1968) | 50-day exposure duration | <i>Mya arenaria</i>   |

Notes:

- (a) The reported values are presented as the amount of COPC in invertebrate tissue divided by the amount of COPC in the water. If the values reported in the studies were presented as dry tissue weight over amount of COPC in water, they were converted to wet weight by dividing the concentration in dry invertebrate tissue weight by 5.99. This conversion factor assumes an invertebrate's total weight is 83.3 percent moisture, which is based on the moisture content of the earthworm (Pietz et al. 1984).

The conversion factor was calculated as follows:

$$\text{Conversion factor} = \frac{1.0 \text{ gram (g) invertebrate total weight}}{1.0 \text{ gram (g) invertebrate total weight} - 0.833 \text{ g invertebrate wet weight}}$$

- (b) Reported field values for organic COPCs are assumed to be total COPC concentration in water and, therefore, were converted to dissolved COPC concentration in water using the following equation from U.S.EPA (1995b):

$$\text{BCF (dissolved)} = (\text{BCF (total)} / f_{\text{fd}}) - 1$$

where: BCF (dissolved) = BCF based on dissolved concentration of COPC in water  
 BCF (total) = BCF based on the field derived data for total concentration of COPC in water  
 $f_{\text{fd}}$  = Fraction of COPC that is freely dissolved in the water

where:  $f_{\text{fd}} = 1 / [1 + ((\text{DOC} \times K_{\text{ow}}) / 10) + (\text{POC} \times K_{\text{ow}})]$   
 DOC = Dissolved organic carbon, kilograms of organic carbon / liter of water ( $2.0 \times 10^{-6}$  Kg/L)  
 $K_{\text{ow}}$  = Octanol-water partition coefficient of the COPC, as reported in U.S. EPA (1994b)  
 POC = Particulate organic carbon, kilograms of organic carbon / liter of water ( $7.5 \times 10^{-9}$  Kg/L)

| Compound: 2,3,4,7,8-Pentachlorodibenzofuran (2,3,4,7,8-PeCDF)                                                                                                                                               |                                         |                         | Recommended BCF value: 5,283 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 3,302 \times 1.6 = 5,283$                                                      |                                         |                         |                              |
| Compound: 1,2,3,4,7,8-Hexachlorodibenzofuran (1,2,3,4,7,8-HxCDF)                                                                                                                                            |                                         |                         | Recommended BCF value: 251.0 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 3,302 \times 0.076 = 251.0$                                                    |                                         |                         |                              |
| Compound: 1,2,3,6,7,8-Hexachlorodibenzofuran (1,2,3,6,7,8-HxCDF)                                                                                                                                            |                                         |                         | Recommended BCF value: 627.4 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 3,302 \times 0.19 = 627.4$                                                     |                                         |                         |                              |
| Compound: 2,3,4,6,7,8-Hexachlorodibenzofuran (2,3,4,6,7,8-HxCDF)                                                                                                                                            |                                         |                         | Recommended BCF value: 2,212 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 3,302 \times 0.67 = 2,212$                                                     |                                         |                         |                              |
| Compound: 1,2,3,7,8,9-Hexachlorodibenzofuran (1,2,3,7,8,9-HxCDF)                                                                                                                                            |                                         |                         | Recommended BCF value: 2,080 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 3,302 \times 0.63 = 2,080$                                                     |                                         |                         |                              |
| Compound: 1,2,3,4,6,7,8-Heptachlorodibenzofuran (1,2,3,4,6,7,8-HpCDF)                                                                                                                                       |                                         |                         | Recommended BCF value: 36.3  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 3,302 \times 0.011 = 36.3$                                                     |                                         |                         |                              |
| Compound: 1,2,3,4,7,8,9-Heptachlorodibenzofuran (1,2,3,4,7,8,9-HpCDF)                                                                                                                                       |                                         |                         | Recommended BCF value: 1,288 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 3,302 \times 0.39 = 1,288$                                                     |                                         |                         |                              |
| Compound: Octachlorodibenzofuran (OCDF)                                                                                                                                                                     |                                         |                         | Recommended BCF value: 52.8  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 3,302 \times 0.016 = 52.8$                                                     |                                         |                         |                              |
| <b>Polynuclear Aromatic Hydrocarbons (PAHs)</b>                                                                                                                                                             |                                         |                         |                              |
| Compound: Benzo(a)pyrene                                                                                                                                                                                    |                                         |                         | Recommended BCF value: 5,258 |
| The recommended BCF value was based on a single measured value for benzo(a)pyrene. This value was also used as a surrogate for all high molecular weight PAHs for which laboratory data were not available. |                                         |                         |                              |
| 5,258                                                                                                                                                                                                       | Lu, Metcalf, Plummer, and Mandel (1977) | 3-day exposure duration | <i>Oedogonium cardiacum</i>  |
| Compound: Benzo(a)anthracene                                                                                                                                                                                |                                         |                         | Recommended BCF value: 5,258 |

| <b>Polychlorinated Biphenyls (PCBs)</b>                                                                                                                                                                                                                                     |                             |                                 |                                |
| Compound: Aroclor 1016                                                                                                                                                                                                                                                      |                             |                                 | Recommended BCF value: 476,829 |
| The reported value was calculated by dividing the wet tissue concentration by the medium concentration (ppm/pptr). A conversion factor of $1 \times 10^6$ was applied to the value. The BCF value is based on Aroclor 1254 since there was no available data for total PCB. |                             |                                 |                                |
| 476,829                                                                                                                                                                                                                                                                     | Scura and Theilacker (1977) | 45-day exposure to Aroclor 1254 | <i>Dunaliella</i> sp.          |
| Compound: Aroclor 1254                                                                                                                                                                                                                                                      |                             |                                 | Recommended BCF value: 476,829 |

Notes:

- (a) The reported values are presented as the amount of COPC in algae divided by the amount of COPC in water. If the values reported in the studies were presented as dry tissue weight over the amount of COPC in water, they were converted to wet weight over dry weight by dividing the concentration in dry algae tissue weight by 2.92. This conversion factor assumes an algae total weight is 65.7 percent moisture (Isensee, Kearney, Woolson, Jones and Williams 1973). The conversion factor was calculated as follows:

$$\text{Conversion factor} = \frac{1.0 \text{ g algae total weight}}{1.0 \text{ g algae total weight} - 0.675 \text{ g algae wet weight}}$$

(Page 3 of 19)

| Reported Values                                                                                                                                                                                                                            | Reference      | Experimental Parameters | Species                      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-------------------------|------------------------------|
| Compound: 1,2,3,4,6,7,8,-Heptachlorodibenzo(p)furan (1,2,3,4,6,7,8-HpCDF)                                                                                                                                                                  |                |                         | Recommended BCF value: 46.6  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 4,235 \times 0.011 = 46.6$                                                                                    |                |                         |                              |
| Compound: 1,2,3,4,7,8,9-Heptachlorodibenzo(p)furan (1,2,3,4,7,8,9-HpCDF)                                                                                                                                                                   |                |                         | Recommended BCF value: 1,651 |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 4,235 \times 0.39 = 1,651$                                                                                    |                |                         |                              |
| Compound: Octachlorodibenzo(p)furan (OCDF)                                                                                                                                                                                                 |                |                         | Recommended BCF value: 67.8  |
| The BCF was calculated using the TCDD BCF and a bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 4,235 \times 0.016 = 67.8$                                                                                    |                |                         |                              |
| <b>Polynuclear Aromatic Hydrocarbons (PAHs)</b>                                                                                                                                                                                            |                |                         |                              |
| Compound: Benzo(a)pyrene                                                                                                                                                                                                                   |                |                         | Recommended BCF value: 500   |
| The recommended value is that presented in Stephan (1993), which was the geometric mean of 16 laboratory values. This BCF for benzo(a)pyrene is also recommended for high molecular weight PAH for which empirical data are not available. |                |                         |                              |
| 500                                                                                                                                                                                                                                        | Stephan (1993) | Not reported            | Not reported                 |
| Compound: Benzo(a)anthracene                                                                                                                                                                                                               |                |                         | Recommended BCF value: 500   |
| Empirical data were not available for this compound. The BCF for benzo(a)pyrene was used as a surrogate.                                                                                                                                   |                |                         |                              |
| Compound: Benzo(b)fluoranthene                                                                                                                                                                                                             |                |                         | Recommended BCF value: 500   |
| Empirical data were not available for this compound. The BCF for benzo(a)pyrene was used as a surrogate.                                                                                                                                   |                |                         |                              |
| Compound: Benzo(k)fluoranthene                                                                                                                                                                                                             |                |                         | Recommended BCF value: 500   |
| Empirical data were not available for this compound. The BCF for benzo(a)pyrene was used as a surrogate.                                                                                                                                   |                |                         |                              |
| Compound: Chrysene                                                                                                                                                                                                                         |                |                         | Recommended BCF value: 500   |
| Empirical data were not available for this compound. The BCF for benzo(a)pyrene was used as a surrogate.                                                                                                                                   |                |                         |                              |
| Compound: Dibenz(a,h)anthracene                                                                                                                                                                                                            |                |                         | Recommended BCF value: 500   |
| Empirical data were not available for this compound. The BCF for benzo(a)pyrene was used as a surrogate.                                                                                                                                   |                |                         |                              |

TABLE C-5

**WATER-TO-FISH BIOCONCENTRATION FACTORS**  
**(mg COPC / kg wet tissue) / (mg dissolved COPC / L water)**

| Compound: Antimony                                                                                                                                                                                                                                                                                          |                                                       |                                             | Recommended BCF value: 40    |
| The recommended BCF value was based on one study as follows:                                                                                                                                                                                                                                                |                                                       |                                             |                              |
| 40                                                                                                                                                                                                                                                                                                          | Thompson, Burton, Quinn, and Ng (1972)                | Not reported                                | Fish                         |
| Compound: Arsenic                                                                                                                                                                                                                                                                                           |                                                       |                                             | Recommended BCF value: 114   |
| The recommended BCF value was calculated using the geometric mean of 3 laboratory values as follows:                                                                                                                                                                                                        |                                                       |                                             |                              |
| 333<br>100                                                                                                                                                                                                                                                                                                  | Thompson, Burton, Quinn, and Ng (1972)                | Not reported                                | Fish                         |
| 44                                                                                                                                                                                                                                                                                                          | U.S. EPA (1992b)                                      | Not reported                                | Fish                         |
| Compound: Barium                                                                                                                                                                                                                                                                                            |                                                       |                                             | Recommended BCF value: 633   |
| Empirical data for this compound were not available. The recommended BCF is the arithmetic mean of the recommended values for 14 inorganics with empirical data available (aluminum, antimony, arsenic, beryllium, cadmium, chromium, copper, lead, mercury, nickel, selenium, silver, thallium, and zinc). |                                                       |                                             |                              |
| Compound: Beryllium                                                                                                                                                                                                                                                                                         |                                                       |                                             | Recommended BCF value: 62    |
| The recommended BCF value was calculated using the geometric mean of 4 laboratory values as follows:                                                                                                                                                                                                        |                                                       |                                             |                              |

| Compound: Cyanide (total)                                                                                                                                                                                                                                                                                   |                                                       |                                                                                                                                                                                                                                                                                   | Recommended BCF value: 633    |
| Empirical data for this compound were not available. The recommended BCF is the arithmetic mean of the recommended values for 14 inorganics with empirical data available (aluminum, antimony, arsenic, beryllium, cadmium, chromium, copper, lead, mercury, nickel, selenium, silver, thallium, and zinc). |                                                       |                                                                                                                                                                                                                                                                                   |                               |
| Compound: Lead                                                                                                                                                                                                                                                                                              |                                                       |                                                                                                                                                                                                                                                                                   | Recommended BCF value: 0.09   |
| The recommended BCF value based on one field value:                                                                                                                                                                                                                                                         |                                                       |                                                                                                                                                                                                                                                                                   |                               |
| 0.09                                                                                                                                                                                                                                                                                                        | Atchinson, Murphy, Bishop, McIntosh, and Mayes (1977) | Field samples. The values reported in Atchinson, Murphy, Bishop, McIntosh, and Mayes (1977) were converted to wet weight using a conversion factor of 5.0 <sup>a</sup> .                                                                                                          | <i>Lepomis macrochirus</i>    |
| 0.15<br>0.17                                                                                                                                                                                                                                                                                                | Holcombe, Benoit, Leonard, and McKim (1976)           | 266-day exposure duration. The values reported in Holcombe, Benoit, Leonard, and McKim (1976) were converted to wet weight using a conversion factor of 5.0 <sup>a</sup> . Mean values were calculated based on tissue concentrations in the red blood cells, kidney, and muscle. | <i>Salvelinus fontinalis</i>  |

## Notes:

- (a) The reported values are presented as the amount of COPC in fish tissue divided by the amount of COPC in water. If the values reported in the studies were presented as dry tissue weight, they were converted to wet weight by dividing the concentration in dry fish tissue weight by 5.0. This conversion factor assumes a fish's total weight is 80.0 percent moisture (Holcomb, Benoit, Leonard, and McKim 1976).

**TABLE C-5**

**WATER-TO-FISH BIOCONCENTRATION FACTORS  
(mg COPC / kg wet tissue) / (mg dissolved COPC / L water)**

**(Page 19 of 19)**

The conversion factor was calculated as follows:

$$\text{Conversion factor} = \frac{1.0 \text{ g fish total weight}}{1.0 \text{ g fish total weight} - 0.80 \text{ g fish wet weight}}$$

- (b) The equation used to convert the total organic COPC concentrations in field samples to dissolved COPC concentrations is from U.S. EPA (1995a) as follows:

$$BAF(\text{dissolved}) = (BAF(\text{total}) / f_{fd}) - 1$$

where:  $BAF(\text{dissolved})$  =  $BAF$  based on dissolved concentration of COPC in water

$BAF(\text{total})$  =  $BAF$  based on the field derived data for total concentration of COPC in water

$f_{fd}$  = Fraction of COPC that is freely dissolved in the water

where:  $f_{fd} = 1 / [1 + ((DOC \times K_{ow}) / 10) + (POC \times K_{ow})]$

$DOC$  = Dissolved organic carbon, Kg of organic carbon / L of water ( $2.0 \times 10^{-06}$  kg/L)

$K_{ow}$  = Octanol-water partition coefficient of the COPC, as reported in U.S. EPA (1994b)

$POC$  = Particulate organic carbon, Kg of organic carbon / L of water ( $7.5 \times 10^{-09}$  Kg/L)

- (c) The reported field  $BAFs$  were converted to  $BCFs$  as follows:

$$BCF = (BAF_{TLn} / FCM_{TLn}) - 1$$

where:  $BAF_{TLn}$  = The reported field bioaccumulation factor for the trophic level “n” of the study species.

$FCM_{TLn}$  = The food chain multiplier for the trophic level “n” of the study species.

- (d) PCB values were converted to dissolved COPC  $BCFs$  based on the  $K_{ow}$  for Aroclor 1254.
- (e) The geometric mean of the converted field derived  $BCFs$  was compared to the geometric mean of the laboratory derived  $BCFs$ . The higher of the two values was selected as the COPC  $BCF$ .

| Reported Values <sup>a</sup>                                                                                                                                                                                                                                   | Reference | Experimental Parameters | Species                       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|-------------------------|-------------------------------|
| <b>Dioxins and Furans</b>                                                                                                                                                                                                                                      |           |                         |                               |
| Compound: 2,3,7,8-Tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD)                                                                                                                                                                                                   |           |                         | Recommended BCF value: 19,596 |
| Empirical data for this compound were not available. The BCF was calculated using the following regression equation:<br>$\log BCF = 0.819 \times \log K_{ow} - 1.146$ (Southworth, Beauchamp, and Schmieder 1978), where $\log K_{ow} = 6.64$ (U.S. EPA 1994a) |           |                         |                               |
| Compound: 1,2,3,7,8-Pentachlorodibenzo(p)dioxin (1,2,3,7,8-PeCDD)                                                                                                                                                                                              |           |                         | Recommended BCF value: 18,023 |
| The BCF was calculated using the TCDD BCF and a congener-specific bioaccumulation equivalency factor (BEF) (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.92 = 3,896$                                                                                     |           |                         |                               |
| Compound: 1,2,3,4,7,8-Hexachlorodibenzo-p-dioxin (1,2,3,4,7,8-HxCDD)                                                                                                                                                                                           |           |                         | Recommended BCF value: 6,075  |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.31 = 1313$                                                                                                                           |           |                         |                               |
| Compound: 1,2,3,6,7,8-Hexachlorodibenzo-p-dioxin (1,2,3,6,7,8-HxCDD)                                                                                                                                                                                           |           |                         | Recommended BCF value: 2,351  |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.12 = 2,351$                                                                                                                          |           |                         |                               |
| Compound: 1,2,3,7,8,9-Hexachlorodibenzo-p-dioxin (1,2,3,7,8,9-HxCDD)                                                                                                                                                                                           |           |                         | Recommended BCF value: 2,743  |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.14 = 2,743$                                                                                                                          |           |                         |                               |
| Compound: 1,2,3,4,6,7,8-Heptachlorodibenzo-p-dioxin (1,2,3,4,6,7,8-HpCDD)                                                                                                                                                                                      |           |                         | Recommended BCF value: 99.4   |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.051 = 99.4$                                                                                                                          |           |                         |                               |
| Compound: Octachlorodibenzo-p-dioxin (OCDD)                                                                                                                                                                                                                    |           |                         | Recommended BCF value: 23.5   |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.012 = 23.5$                                                                                                                          |           |                         |                               |
| Compound: 2,3,7,8-Tetrachlorodibenzofuran (2,3,7,8-TCDF)                                                                                                                                                                                                       |           |                         | Recommended BCF value: 2,642  |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 3,302 \times 0.80 = 2,642$                                                                                                                           |           |                         |                               |
| Compound: 1,2,3,7,8-Pentachlorodibenzo-p-furan (1,2,3,7,8-PeCDF)                                                                                                                                                                                               |           |                         | Recommended BCF value: 4,311  |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.22 = 4,311$                                                                                                                          |           |                         |                               |
| Compound: 2,3,4,7,8-Pentachlorodibenzo-p-furan (2,3,4,7,8-PeCDF)                                                                                                                                                                                               |           |                         | Recommended BCF value: 31,354 |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 1.6 = 31,354$                                                                                                                          |           |                         |                               |

|----------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|-------------------------------|--------------------------------------------------------------------------------------------|
| Compound: 1,2,3,4,7,8-Hexachlorodibenzo-p-furan (1,2,3,4,7,8-HxCDF)                                                                    |                                               |                               | Recommended BCF value: 1,489                                                               |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.076 = 1,489$ |                                               |                               |                                                                                            |
| Compound: 1,2,3,6,7,8-Hexachlorodibenzo-p-furan (1,2,3,6,7,8-HxCDF)                                                                    |                                               |                               | Recommended BCF value: 3,723                                                               |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.19 = 3,723$  |                                               |                               |                                                                                            |
| Compound: 2,3,4,6,7,8-Hexachlorodibenzo-p-furan (2,3,4,6,7,8-HxCDF)                                                                    |                                               |                               | Recommended BCF value: 13,129                                                              |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.67 = 13,129$ |                                               |                               |                                                                                            |
| Compound: 1,2,3,7,8,9-Hexachlorodibenzo-p-furan (1,2,3,7,8,9-HxCDF)                                                                    |                                               |                               | Recommended BCF value: 12,345                                                              |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.63 = 12,345$ |                                               |                               |                                                                                            |
| Compound: 1,2,3,4,6,7,8-Heptachlorodibenzo-p-furan (1,2,3,4,6,7,8-HpCDF)                                                               |                                               |                               | Recommended BCF value: 215.6                                                               |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.011 = 215.6$ |                                               |                               |                                                                                            |
| Compound: 1,2,3,4,7,8,9-Heptachlorodibenzo-p-furan (1,2,3,4,7,8,9-HpCDF)                                                               |                                               |                               | Recommended BCF value: 7,642                                                               |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.39 = 7,642$  |                                               |                               |                                                                                            |
| Compound: Octachlorodibenzo-p-furan (OCDF)                                                                                             |                                               |                               | Recommended BCF value: 313.5                                                               |
| The BCF was calculated using the TCDD BCF and a congener-specific BEF (U.S. EPA 1995b) as follows: $BCF = 19,596 \times 0.016 = 313.5$ |                                               |                               |                                                                                            |
| <b>Polynuclear Aromatic Hydrocarbons (PAHs)</b>                                                                                        |                                               |                               |                                                                                            |
| Compound: Benzo(a)pyrene                                                                                                               |                                               |                               | Recommended BCF value: 1.59                                                                |
| The recommended BCF value was calculated using the geometric mean of 8 values as follows:                                              |                                               |                               |                                                                                            |

| Compound: Beryllium                                                                                                                                                                                                                   |                              |                                                     |                                                                                                                                                                                                                                                                                                                      | Recommended BCF value: 0.90   |
| Empirical data for this compound were not available. The recommended BCF value is the arithmetic average of 6 recommended values for those metals with empirical data (cadmium, chromium, copper, lead, inorganic mercury, and zinc). |                              |                                                     |                                                                                                                                                                                                                                                                                                                      |                               |
| Compound: Cadmium                                                                                                                                                                                                                     |                              |                                                     |                                                                                                                                                                                                                                                                                                                      | Recommended BCF value: 3.4    |
| The recommended BCF value was calculated using the geometric mean of 8 field-derived values as follows:                                                                                                                               |                              |                                                     |                                                                                                                                                                                                                                                                                                                      |                               |

**TABLE C-6**

**SEDIMENT-TO-BENTHIC INVERTEBRATE BIOCONCENTRATION FACTORS  
(mg COPC / kg wet tissue) / (mg COPC / kg dry sediment)**

**(Page 11 of 11)**

Notes:

- (a) The reported values are presented as the amount of compound in invertebrate tissue divided by the amount of compound in the sediment. If the values reported in the studies were presented as dry tissue weight over dry sediment weight, they were converted to wet weight over dry weight by dividing the concentration in dry invertebrate tissue weight by 5.99. This conversion factor assumes an earthworm's total weight is 83.3 percent moisture (Pietz et al. 1984).

The conversion factor was calculated as follows:

$$\text{Conversion factor} = \frac{1.0 \text{ g invertebrate total weight}}{1.0 \text{ g invertebrate total weight} - 0.833 \text{ g invertebrate wet weight}}$$

---

TABLE C-7

**AIR-TO-PLANT BIOTRANSFER FACTORS**  
**(µg COPC / g dry plant) / (µg COPC / g air)**

(Page 3 of 3)

| Compound              | Bv Value <sup>a</sup> | Compound | Bv Value |
|-----------------------|-----------------------|----------|----------|
| Cadmium               | 0                     | Silver   | 0        |
| Chromium (hexavalent) | 0                     | Thallium | 0        |
| Copper                | 0                     | Zinc     | 0        |
| Cyanide (total)       | 0                     |          |          |

Notes:

- (a) The reported values were obtained from the references cited in Section C-1.7, and are consistent with the values provided in U.S. EPA (1998). Values for dioxin and furan congeners were obtained from the following:

Lorber, M., and P. Pinsky. 1999. "An Evaluation of Three Empirical Air-to-Leaf Models for Polychlorinated Dibenzo-p-Dioxins and Dibenzofurans." National Center for Environmental Assessment (NCEA). U. S. EPA, 401 M St. SW, Washington, DC. *Accepted for Publication in Chemosphere.*

## APPENDIX D

### WILDLIFE MEASUREMENT RECEPTOR *BCF*s

Appendix D provides recommended guidance for determining values for compound-specific, media to receptor, bioconcentration factors (*BCF*s) for wildlife measurement receptors. Wildlife measurement receptor *BCF*s should be based on values reported in the scientific literature, or estimated using physical and chemical properties of the compound. Guidance on use of *BCF* values in the screening level ecological risk assessment is provided in Chapter 5.

Section D-1.0 provides the general guidance recommended to select or estimate compound *BCF* values for wildlife measurement receptors. Sections D-1.0 through D-1.3 further discuss determination of *BCF*s for specific media and receptors. References cited in Sections D-1.1 through D-1.3 are located following Section D-1.3.

For the compounds commonly identified in risk assessments for combustion facilities (identified in Chapter 2) and the mammal and bird example measurement receptors listed in Chapter 4, *BCF* values have been determined following the guidance in Sections D-1.0 through D-1.3. *BCF* values for these limited number of compounds and pathways are included in this appendix (see Tables D-1 through D-3) to facilitate the completion of screening ecological risk assessments. However, it is expected that *BCF* values for additional compounds and receptors may be required for evaluation on a site specific basis. In such cases, *BCF* values for these additional compounds could be determined following the same guidance (Sections D-1.0 through D-1.3) used in determination of the *BCF* values reported in this appendix. For the calculation of *BCF* values for measurement receptors not represented in Sections D-1.1 through D-1.3 (e.g., amphibians and reptiles), an approach consistent to that presented in this appendix could be utilized by applying data applicable to those measurement receptors being evaluated.

For additional discussion on some of the references and equations cited in Sections D-1.0 through D-1.3, the reader is recommended to review the Human Health Risk Assessment Protocol (HHRAP) (U.S. EPA 1998) (see Appendix A-3), and the source documents cited in the reference section of this appendix.

#### D-1.0 GENERAL GUIDANCE

This section describes general procedures for developing compound-specific *BCF*s from biotransfer factors (*Ba*) for assessing exposure of measurement receptors. A biotransfer factor is the ratio of the compound concentration in fresh (wet) weight animal tissue to the daily intake of compound by the animal through ingestion of food items and media (soil, sediment, surface water). Therefore, as discussed in Chapter 5, biotransfer factors and receptor-specific ingestion rates can be used to calculate food item- and media-to-animal *BCF*s. This approach provides an estimate of biotransfer of compounds from applicable food items and media to measurement receptors ingesting these items.

Biotransfer factors could also be used directly in equations to calculate dose to measurement receptors. However, in order to promote consistency in evaluating exposure across all trophic levels within complex food webs, *BCF*s calculated from *Ba* values are recommended in this guidance for evaluating measurement receptors. The use of *Ba* values to determine *BCF* values, and the use of *BCF* values in general, for the estimation of compound concentrations in measurement receptors may introduce

uncertainty. Major factors that influence the uptake of a compound by an animal, and therefore uncertainty, include bioavailability, metabolic rate, type of digestive system, and feeding behavior. Uncertainties also should be considered regarding the development of biotransfer values in comparison to how they are being applied for estimating exposure. For example, biotransfer values may be used to estimate contaminant uptake to species from items ingested that differ from the species and intakes used to empirically develop the values. Also, biotransfer data reported in literature may be specific to tissue or organ analysis versus whole body. As a result, BCFs may be under- or over-estimated to an unknown degree.

**BCFs for Measurement Receptors Ingesting Food Items** BCF values for measurement receptors ingesting food items (plants or prey) can be calculated using the compound specific  $Ba$  value applicable to the animal (e.g., mammal, bird, etc.) and the measurement receptor-specific ingestion rate as follows:

$$BCF_{F-A} = Ba_A \cdot IR_F \quad \text{Equation D-1-1}$$

where

|             |   |                                                                                                                                           |
|-------------|---|-------------------------------------------------------------------------------------------------------------------------------------------|
| $BCF_{F-A}$ | = | Bioconcentration factor for food item (plant or prey)-to-animal (measurement receptor) [(mg COPC/kg FW tissue)/(mg COPC/kg FW food item)] |
| $Ba_A$      | = | COPC-specific biotransfer factor applicable for the animal (day/kg FW tissue)                                                             |
| $IR_F$      | = | Measurement receptor food item ingestion rate (kg FW/day)                                                                                 |

As an example of applying the above equation, BCF values for plants-to-wildlife measurement receptors listed in Chapter 4 are provided in Table D-1 at the end of this appendix. Measurement-receptor specific ingestion rates used to calculate BCFs are presented in Table 5-1.  $Ba$  values applicable to the mammal and bird measurement receptors in Table D-1 are discussed in Sections D-1.1 and D-1.2, respectively.

**BCFs for Measurement Receptors Ingesting Media** BCF values for measurement receptors in trophic levels 2, 3, and 4 ingesting media (i.e., soil, surface water, and sediment) can be calculated using the compound specific  $Ba$  value applicable to the animal (e.g., mammal, bird, etc.) and the measurement receptor-specific ingestion rate as follows:

$$BCF_{M-A} = Ba_A \cdot IR_M \quad \text{Equation D-1-2}$$

where

|             |   |                                                                                                                         |
|-------------|---|-------------------------------------------------------------------------------------------------------------------------|
| $BCF_{M-A}$ | = | Bioconcentration factor for media-to-animal (measurement receptor) [(mg COPC/kg FW tissue)/(mg COPC/kg WW or DW media)] |
| $Ba_A$      | = | COPC-specific biotransfer factor applicable for the animal (day/kg FW tissue)                                           |

$$IR_M = \text{Measurement receptor media ingestion rate (WW or DW kg/day)}$$

Equation D-1-2 assumes that  $Ba_A$  provides a reasonable estimate of the uptake of a compound from incidental ingestion of abiotic media during foraging.

As an example of applying the above equation, BCF values for various wildlife measurement receptors listed in Chapter 4 are provided in Table D-2 (water) and Table D-3 (soil and sediment). Measurement-receptor specific ingestion rates used to calculate BCFs are presented in Table 5-1.  $Ba$  values applicable to the mammal and bird measurement receptors for which values were calculated are discussed in Sections D-1.1 and D-1.2, respectively.

**BCFs for Dioxins and Furans** As discussed in Chapter 2, the BCF values for PCDDs and PCDFs are calculated using bioaccumulation equivalency factors (BEFs). Consistent with U.S. EPA (1995b), BEFs are expressed relative to the BCF for 2,3,7,8-TCDD as follows:

$$BCF_j = BCF_{2,3,7,8-TCDD} \cdot BEF_j \quad \text{Equation D-1-3}$$

where

$$\begin{aligned} BCF_j &= \text{Food item-to-animal or media-to-animal BCF for } j\text{th PCDD or PCDF congener for food item-to-animal pathway [(mg COPC/kg FW tissue)/(mg COPC/kg FW plant)] or media-to-animal pathway [(mg COPC/kg FW tissue)/(mg COPC/kg WW media)]} \\ BCF_{2,3,7,8-TCDD} &= \text{Food item-to-animal or media-to-animal BCF for 2,3,7,8-TCDD} \\ BEF_j &= \text{Bioaccumulation equivalency factor for } j\text{th PCDD or PCDF congener (unitless)} \end{aligned}$$

The use of BEFs for dioxin and furan congeners is further discussed in Chapter 2.

### D-1.1 BIOTRANSFER FACTORS FOR MAMMALS ( $Ba_{mammal}$ )

As discussed in Section D-1.0, calculation of BCF values to be used in pathways for mammals ingesting food items and media requires the determination of COPC-specific biotransfer factors for mammal measurement receptors ( $Ba_{mammal}$ ). This section discusses selection of the  $Ba_{mammal}$  values used to calculate the COPC and measurement receptor specific BCF values presented in Tables D-1 through D-3.

**Organics** For organics (except PCDDs and PCDFs), the following correlation equation from Travis and Arms (1988) was used to derive  $Ba_{mammal}$  values on a FW basis:

$$\log Ba_{mammal} = -7.6 + \log K_{ow} \quad \text{Equation D-1-4}$$

where

$$\begin{array}{ll} Ba_{mammal} & = \text{Biotransfer factor for mammals (day/kg FW tissue)} \\ K_{ow} & = \text{Octanol-water partition coefficient (unitless)} \end{array}$$

To calculate the values presented in Tables D-1 through D-3, COPC-specific  $K_{ow}$  values were obtained from Appendix A-2.

Biotransfer factors obtained from Travis and Arms (1988) were derived from correlation equations developed from data on experiments conducted with beef cattle ingesting food items and media containing compound classes such as DDT, pesticides, PCDDs, PCDFs, and PCBs. As further literature is developed for other species and compounds, the Travis and Arms (1988) correlation equation should be compared for applicability to species and compound, and best fit correlation for estimation of uptake.

**PCDDs and PCDFs**  $Ba_{mammal}$  values for PCDD and PCDFs were derived from  $Ba$  values for cattle as presented in:

- U.S. EPA 1995a. "Further Studies for Modeling the Indirect Exposure Impacts from Combustor Emissions." Memorandum from Matthew Lorber, Exposure Assessment Group, and Glenn Rice, Environmental Criteria and Assessment Office, Washington, D.C. January 20.

U.S. EPA (1995a) determined  $Ba$  values for cattle from McLachlan, Thoma, Reissinger, and Hutzinger (1990). These empirically determined  $Ba$  values were recommended by U.S. EPA (1995a) over the Travis and Arms (1988) correlation equation for dioxins and furans.

**Inorganics** For metals (except cadmium, mercury, selenium, and zinc),  $Ba$  values on a fresh weight basis were obtained from Baes, Sharp, Sjoreen, and Shor (1984). For cadmium, selenium, and zinc, U.S. EPA (1995a) indicated that  $Ba$  values were derived by dividing uptake slopes [(g compound/kg DW tissue)/(g compound/kg DW feed)], obtained from U.S. EPA (1992), by a daily consumption rate of 20 kilograms DW per day by cows.

For use in calculating  $BCF$  values presented in Tables D-1 through D-3 of this appendix, dry weight  $Ba$  values were converted to fresh weight basis by assuming a tissue moisture content (by mass) of 70 percent for cows. Moisture content information was obtained from the following:

- U.S. EPA. 1997a. *Exposure Factors Handbook*. "Food Ingestion Factors". Volume II. EPA/600/P-95/002Fb. August.
- Pennington, J.A.T. 1994. *Food Value of Portions Commonly Used*. Sixteenth Edition. J.B. Lippincott Company, Philadelphia.

**Mercuric Compounds** Based on assumptions made regarding speciation and fate and transport of mercury from stack emissions (as discussed in Chapter 2), elemental mercury is assumed not to deposit onto soils, water, or plants. Therefore, it is also not available in food items or media for ingestion and subsequent uptake by measurement receptors. As a result, no  $BCF$  values for elemental mercury are

presented in Tables D-1 through D-3 of this appendix. If site-specific field data suggest otherwise,  $Ba$  values for elemental mercury can be derived from uptake slope factors provided in U.S. EPA (1992) and U.S. EPA (1995a), using the same consumption rates as were discussed earlier for the metals like cadmium, selenium, and zinc.

$Ba_{mammal}$  values for mercuric chloride and methyl mercury were derived from data in U.S. EPA (1997b). U.S. EPA (1997b) provides  $Ba$  values for mercury in cows, but does not specify the form of mercury. To obtain the  $Ba$  values for mercuric chloride and methyl mercury presented in Tables D-1 through D-3 of this guidance, consistent with U.S. EPA (1997b) total mercury was assumed to be composed of 87 percent divalent mercury (as mercuric chloride) and 13 percent methyl mercury in herbivore animal tissue. Also, assuming that the  $Ba$  value provided in U.S. EPA (1997b) is for the total mercury in the animal tissue, then biotransfer factors in U.S. EPA (1997b) can be determined for mercuric chloride and methyl mercury, as follows:

- The default  $Ba$  value of 0.02 day/kg DW for total mercury obtained from U.S. EPA (1997b) was converted to a fresh weight basis assuming a 70 percent moisture content in cow tissue (U.S. EPA 1997a; Pennington 1994). The fresh weight  $Ba$  value for total mercury was multiplied by 0.13 to obtain a  $Ba_{mammal}$  value for methyl mercury, and by 0.87 to obtain a  $Ba_{mammal}$  value for mercuric chloride.

#### D-1.2 BIOTRANSFER FACTORS FOR BIRDS ( $Ba_{bird}$ )

As discussed in Section D-1.0, calculation of  $BCF$  values to be used in pathways for birds ingesting food items and media requires the determination of COPC-specific biotransfer factors for bird measurement receptors ( $Ba_{bird}$ ). This section discusses selection of the  $Ba_{bird}$  values used to calculate the COPC and measurement receptor specific  $BCF$  values presented in Tables D-1 through D-3.

**Organics**  $Ba_{bird}$  values for organic compounds (except PCDDs and PCDFs) were derived from  $Ba_{mammal}$  values by assuming that the lipid content (by mass) of birds and mammals is 15 and 19 percent, respectively. Therefore,  $Ba_{bird}$  values presented in Tables D-1 through D-3 were determined by multiplying  $Ba_{mammal}$  values by the bird and mammal fat content ratio of 0.8 (15/19).

Notable uncertainties associated with this approach include (1) extent to which specific organic compounds bioconcentrate in fatty tissues, and (2) differences in lipid content, metabolism, and feeding characteristics between species.

**PCDDs and PCDFs**  $Ba_{bird}$  values presented in Tables D-1 through D-3 for PCDD and PCDF congeners were derived from data provided in the following:

- Stephens, R.D., M. Petreas, and G.H. Hayward. 1995. "Biotransfer and Bioaccumulation of Dioxins and Furans from Soil: Chickens as a Model for Foraging Animals." *The Science of the Total Environment*. Volume 175. Pages 253-273.

Stephens, Petreas, and Hayward (1995) conducted experiments to determine the bioavailability and the rate of PCDDs and PCDFs uptake from soil by foraging chickens. Three groups of White Leghorn

chickens were studied—control group, low exposure group, and high exposure group. Eggs, tissues (liver, adipose, and thigh), feed, and feces were analyzed.

Congener specific  $Ba_{bird}$  values were derived from the Stephens, Petreas, and Hayward (1995) study by dividing estimated whole body bioconcentration values for the high exposure group by a daily consumption rate of soil. If congener specific BCF values were not reported for the high exposure group, then estimated whole body values were determined using reported data for the low exposure group, if available. A default consumption rate of soil by chicken of 0.02 kg DW/day was determined as follows:

- (1) Consumption rate of feed by chicken was obtained from U.S. EPA (1995a), which cites a value of 0.2 kg (DW) feed/day obtained from various literature sources.
- (2) The fraction of feed that is soil (0.1) was obtained from Stephens, Petreas, and Hayward (1995).
- (3) Feed consumption rate of 0.2 kg/day was multiplied by fraction of feed that is soil (0.1), to obtain the soil consumption rate by chicken of  $0.2 \times 0.1 = 0.02$  kg DW soil/day.

**Inorganics** For metals (except cadmium, selenium, and zinc),  $Ba_{bird}$  values were not available in the literature. For cadmium, selenium, and zinc, U.S. EPA (1995a) cites  $Ba$  values that were derived by dividing uptake slopes [(g compound/kg dry DW tissue)/(g compound/kg DW feed)], obtained from U.S. EPA (1992), by a daily ingestion rate of 0.2 kilograms DW per day by poultry. To determine BCF values presented in Tables D-1 through D-3 in this appendix, reported dry weight  $Ba$  values were converted to fresh weight basis by assuming a tissue moisture content (by mass) of 75 percent for poultry (U.S. EPA 1997a; Pennington 1994).

**Mercuric Compounds** Based on assumptions made regarding speciation and fate and transport of mercury from stack emissions (as discussed in Chapter 2), elemental mercury is assumed not to deposit onto soils, water, or plants. Therefore, it is also not available in food items or media for ingestion and subsequent uptake by measurement receptors. As a result, no BCF values for elemental mercury are presented in Tables D-1 through D-3 of this appendix. If site-specific field data suggest otherwise,  $Ba$  values for elemental mercury can be derived from uptake slope factors provided in U.S. EPA (1992) and U.S. EPA (1995a), using the same consumption rates as were discussed earlier for the metals like cadmium, selenium, and zinc.

$Ba_{bird}$  values for mercuric chloride and methyl mercury were derived from data in U.S. EPA (1997b). U.S. EPA (1997b) provides  $Ba$  values for mercury in poultry, but does not specify the form of mercury. To obtain the  $Ba$  values for mercuric chloride and methyl mercury presented in Tables D-1 through D-3 of this guidance, consistent with U.S. EPA (1997b) total mercury was assumed to be composed of 87 percent divalent mercury (as mercuric chloride) and 13 percent methyl mercury in herbivore animal tissue. Also, assuming that the  $Ba$  value provided in U.S. EPA (1997b) is for the total mercury in the animal tissue, then biotransfer factors in U.S. EPA (1997b) can be determined for mercuric chloride and methyl mercury, as follows:

- The default *Ba* value of 0.02 day/kg DW for total mercury obtained from U.S. EPA (1997b) was converted to a fresh weight basis assuming a 75 percent moisture content in poultry tissue (U.S. EPA 1997a; Pennington 1994). The fresh weight *Ba* value for total mercury was multiplied by 0.13 to obtain a *Ba<sub>bird</sub>* value for methyl mercury, and by 0.87 to obtain a *Ba<sub>bird</sub>* value for mercuric chloride.

Notes:

NA - Indicates insufficient data to determine value

HB - Herbivorous bird

HM - Herbivorous mammal

OB - Omnivorous bird

OM - Omnivorous mammal

TP - Terrestrial plant

– Values provided were determined as specified in the text of Appendix D. *BCF* values for omnivores were determined based on an equal diet. *BCF* values for dioxin and furan congeners determined using BEF values specified in Chapter 2.

Table D-2

## Bioconcentration Factors for Water to Wildlife Measurement Receptors

(Page 1 of 6)

Notes:

NA - Indicates insufficient data to determine value

HB - Herbivorous bird

HM - Herbivorous mammal

OB - Omnivorous bird

OM - Omnivorous mammal

TP - Terrestrial plant

– Values provided were determined as specified in the text of Appendix D. BCF values for omnivores were determined based on an equal diet. BCF values for dioxin and furan congeners determined using BEF values specified in Chapter 2.

Table D-2

## Notes:

NA - Indicates insufficient data to determine value

HB - Herbivorous bird

HM - Herbivorous mammal

OB - Omnivorous bird

OM - Omnivorous mammal

TP - Terrestrial plant

- Values provided were determined as specified in the text of Appendix D. *BCF* values for omnivores were determined based on an equal diet. *BCF* values for dioxin and furan congeners determined using BEF values specified in Chapter 2.

TABLE D-3

## BIOCONCENTRATION FACTORS FOR SOIL/SEDIMENT TO WILDLIFE MEASUREMENT RECEPTORS

Notes:

NA - Indicates insufficient data to determine value

HB - Herbivorous bird  
 HM - Herbivorous mammal  
 OB - Omnivorous bird  
 OM - Omnivorous mammal  
 S - Soil/Sediment

- Values provided were determined as specified in the text of Appendix D. BCF values for omnivores were determined based on an equal diet. BCF values for dioxin and furan congeners determined using BEF values specified in Chapter 2.

TABLE D-3

## BIOCONCENTRATION FACTORS FOR SOIL/SEDIMENT TO WILDLIFE MEASUREMENT RECEPTORS

(Page 4 of 6)

Notes:

NA - Indicates insufficient data to determine value

HB - Herbivorous bird  
 HM - Herbivorous mammal  
 OB - Omnivorous bird  
 OM - Omnivorous mammal  
 S - Soil/Sediment

- Values provided were determined as specified in the text of Appendix D. BCF values for omnivores were determined based on an equal diet. BCF values for dioxin and furan congeners determined using BEF values specified in Chapter 2.

## APPENDIX E

### TOXICITY REFERENCE VALUES

Appendix E presents implementation of the recommended approach (described in Chapter 5) for identifying toxicity reference values (*TRVs*) for measurement receptors. Discussion is provided for determining compound-specific *TRV* values for community and wildlife measurement receptors.

Following the guidance in Sections E-1.0 through E-1.2, U.S. EPA OSW has identified default *TRV* values for the measurement receptors of the seven example food webs (listed in Chapter 4) and the compounds commonly identified in ecological risk assessments for combustion facilities (identified in Chapter 2). Section E-1.0 describes the determination of *TRV* values for surface water, sediment, and soil community measurement receptors in the example food webs. Section E-2.0 describes determination of *TRV* values for wildlife measurement receptors in the example food webs. Tables E-1 through E-8 present the default *TRV* values selected, the basis for selection of each value, and the references evaluated in determination of each value.

*TRV* values for a limited number of compounds are included in this appendix (see Tables E-1 through E-3) to facilitate the completion of screening ecological risk assessments. However, it is expected that *TRV* values for additional compounds and receptors may be required for evaluation on a site specific basis. In such cases, *TRV* values for these additional compounds could be determined following the same guidance used in determination of the *TRV* values reported in this appendix. For the determination of *TRV* values for measurement receptors not specifically represented in Sections E-1.0 through E-2.0 (e.g., amphibians and reptiles), an approach consistent to that presented in this appendix could be utilized by applying data applicable to those measurement receptors being evaluated.

The default *TRVs* provided in Tables E-1 through E-8 are based on values reported in available scientific literature. Toxicity values identified in secondary reference sources were verified, where possible, by reviewing the primary reference source. As noted in Chapter 5, *TRV* values may change as additional toxicity research is conducted and the availability of toxicity data in the scientific literature increases. As a result, U.S. EPA OSW recommends evaluating the latest toxicity data before completing a risk assessment to ensure that the toxicity data used in the risk assessment is the most current. If more appropriate *TRV* values can be documented, they should be used presented to the respective permitting authority for approval.

*TRVs* were not identified for amphibians and reptiles because of the paucity of toxicological information on these receptors. Additional guidance on determination and use of *TRV* values in the screening level ecological risk assessment is provided in Chapter 5.

#### **E-1.0 *TRVs* FOR COMMUNITY MEASUREMENT RECEPTORS IN SURFACE WATER, SEDIMENT, AND SOIL**

*TRV* values provided in this appendix for community measurement receptors in surface water, sediment, and soil were identified from screening toxicity values developed and/or adopted by federal and/or state regulatory agencies. As discussed in Chapter 5, these screening toxicity values are generally provided in the form of standards, criteria, guidance, or benchmarks. For compounds with no available screening toxicity value, *TRVs* were determined using toxicity values from available scientific literature. The

equilibrium partitioning (EqP) approach was used to compute several sediment *TRVs*. Uncertainty factors (UFs) were applied to toxicity values, as necessary, to meet the *TRV* criteria discussed in Chapter 5. The following sections discuss determination of *TRV* values for community receptors in surface water, sediment, and soil.

***Freshwater TRVs*** Freshwater *TRVs* should be used for freshwater and estuarine ecosystems with a salinity less than 5 parts per thousand. Freshwater *TRVs*, based on the dissolved concentration of the compound in surface water, are listed in Table E-1. *TRVs* were identified using the following hierarchy:

1. Federal chronic ambient water quality criteria (AWQC) calculated for with no final residue value (U.S. EPA 1999; 1996b). Federal AWQC for cadmium, copper, lead, nickel, and zinc were multiplied by a chemical-specific conversion factor to determine a *TRV* based on dissolved concentration (U.S. EPA 1999; 1996b).
2. Final chronic values (FCV) for COPCs for which their AWQC included a final residue value (U.S. EPA 1996b).
3. If inadequate data (insufficient number of families of aquatic life with toxicity data) were available to compute an AWQC or FCV, U.S. EPA (1999; 1996b) also reported secondary chronic values (SCV) calculated using the Tier II method in the Great Lakes Water Quality Initiative (GLWQI) (reported in 40 CFR Part 122). This method is similar to the procedures for calculating an FCV. It uses statistically-derived “adjustment factors” to address deficiencies in available data. The adjustment factor decreases as the number of representative families increases.
4. If an AWQC, FCV, or GLWQI Tier II SCV value were not available, toxicity values cited by U.S. EPA (1987) were identified. These toxicity values represent the lowest available values. Further, additional toxicity values available from the AQUIRE database in U.S. EPA’s *ECOTOXicology Database System* (U.S. EPA 1996a) were identified. If collected from a secondary source (such as AQUIRE), original studies were obtained and reviewed for accuracy. The toxicity values reported in Table E-1 represent the lowest (most conservative), ecologically relevant, available value.
5. If toxicity data were unavailable, a surrogate *TRV* from a COPC with a similar structure was identified.
6. If no surrogate was available, a *TRV* was not listed. The potential toxicity of a COPC with no *TRV* should be addressed as an uncertainty (see Chapter 6)

Standard AQUIRE report summaries on tests were screened for duration, endpoint, effect, and concentration. Studies were also screened for ecologically relevant effects by focusing on studies that evaluated effects on survival, reproduction, and growth. Aspects of endpoint, duration, and test organism in each toxicity study were evaluated to identify the most appropriate study. Several compounds, most notably metals, had a large number of toxicity values based on various endpoints, organisms, and exposure durations. In these instances, best scientific judgment was used to identify the most appropriate toxicity value (see Chapter 5).

Chronic NOAEL-based values were not adjusted, but rather were carried through unchanged to become the *TRV*. Toxicity values identified as “less than” a particular concentration were divided by 2 to represent an average value because the true value is unknown, and it occurs between 0 and the noted concentration. *UFs* discussed in Chapter 5 were applied to toxicity values not meeting *TRV* criteria.

**Saltwater TRVs** Saltwater *TRVs* are applicable to marine water bodies and estuarine systems with a salinity greater than 5 ppt. Saltwater *TRVs* are listed in Table E-2. Saltwater water *TRV* development followed the same procedure as described above for freshwater receptors, except no GLWQI Tier II SCVs were available. In addition, if no saltwater *TRV* for a surrogate compound was available, the corresponding freshwater *TRV* was adopted.

**Freshwater Sediment TRVs** Freshwater sediment *TRVs* are listed in Table E-3. They are applicable to water bodies with a salinity less than 5 ppt. Freshwater sediment *TRVs* were identified from various sets of screening values and ecotoxicity review documents. The lowest available screening values among the following sources were identified:

1. No effect level (NEL) and lowest effect level (LEL) values from “Ontario’s Approach to Sediment Assessment and Remediation” (Persaud et al. 1993)
2. Apparent effects threshold (AET) values for the amphipod, *Hyallela azteca*, reported in “Creation of Freshwater Sediment Quality Database and Preliminary Analysis of Freshwater Apparent Effects Thresholds” (Washington State Department of Ecology 1994)
3. Sediment effect concentrations jointly published by the National Biological Service and the U.S. EPA (Ingersoll et al. 1996).

If a screening value was not available in the sources listed above, toxicity studies and other values compiled and reported by Jones, Hull, and Suter (1997) were reviewed to identify possible *TRVs*. Relevant studies were prioritized based on the criteria listed in Chapter 5, and uncertainty factors were applied, as applicable, based on criteria presented (see Chapter 5).

If a screening or sediment toxicity value was not available for an organic COPC, a freshwater sediment *TRV* was computed, using the EqP approach (see Chapter 5), from the compounds corresponding freshwater *TRV* and  $K_{oc}$  value. The U.S. EPA Office of Water utilizes the EqP approach to develop sediment quality criteria for nonionic (neutral) organic chemicals (U.S. EPA 1993). The EqP approach assumes that the toxicity of a compound in sediment is a function of the concentration in pore water and that to be nontoxic, the pore water must meet the surface water final chronic value. The EqP approach also assumes that the concentration of a compound in sediment pore water depends on the carbon content of the sediment and the compound’s organic carbon partitioning coefficient (U.S. EPA 1993). A *TRV* may be calculated using the following equation (U.S. EPA 1993):

$$TRV_{sed} = K_{oc} \cdot f_{oc} \cdot TRV_{sw} \quad \text{Equation E-1}$$

where

$$TRV_{sed} = \text{Sediment } TRV \text{ (}\mu\text{g/kg)}$$

|            |   |                                                                             |
|------------|---|-----------------------------------------------------------------------------|
| $K_{oc}$   | = | Organic carbon partition coefficient (L/kg)                                 |
| $f_{oc}$   | = | Fraction of organic carbon in sediment (unitless)—default value = 4% (0.04) |
| $TRV_{sw}$ | = | Corresponding surface water $TRV$ ( $\mu\text{g/L}$ )                       |

**Marine Sediment TRVs** Marine sediment  $TRVs$  are listed in Table E-4. They are applicable to sediments of marine water bodies and estuarine systems with a salinity greater than 5 ppt. Marine sediment  $TRVs$  were developed following the procedures used to identify the freshwater sediment  $TRVs$ . Screening values were compiled from the following sources:

1. No observed effect level (NOEL) sediment quality assessment guidelines for State of Florida coastal waters (MacDonald 1993).
2. Marine and estuarine effects range low (ERL) values from “Incidence of Adverse Biological Effects Within Ranges of Chemical Concentrations in Marine and Estuarine Sediments” (Long et al. 1995)
3. ERL values from “The Potential for Biological Effects of Sediment-Sorbed Contaminants Tested in the National Status and Trends Program” (Long and Morgan 1991)
4. Marine sediment quality criteria from “Sediment Management Standards” (Washington State Department of Ecology 1991)

Screening values were adopted directly as  $TRVs$ . If a screening value was not available in the sources listed above, toxicity values from a search of the scientific literature and those compiled and reported by Hull and Suter (1994) were reviewed to identify possible  $TRVs$ . Original studies were obtained, where possible, and toxicity values were verified. Relevant studies were prioritized based on the criteria listed in Chapter 5, and uncertainty factors were applied, as appropriate, based on criteria (see Chapter 5). If a screening or ecologically relevant sediment toxicity value from the scientific literature were not available for an organic COPC, a marine sediment  $TRV$  was computed, using the EqP approach, from the COPC’s corresponding saltwater  $TRV$  and  $K_{oc}$  value (see Equation E-1).

**Terrestrial Plant TRVs** The terrestrial plant  $TRVs$  listed in Table E-5 are based on bulk soil exposures. Available terrestrial plant toxicity values from the scientific literature were used to develop presented  $TRV$  values. Toxicity values were first identified from the following secondary sources:

1. Studies cited in *Toxicological Benchmarks for Screening Potential Contaminants of Concern for Effects on Terrestrial Plants: 1997 Revision* (Efroymson, Will, Suter, and Wooten 1997). Available studies were obtained and reviewed for accuracy of toxicity values. UFs were applied depending on study endpoint and available information.
2. Toxicity values in the Phytotox database in U.S. EPA’s *ECOTOXicology Database System*. Available studies were obtained and toxicity values were verified. UFs were applied depending on study endpoint and available information.
3. Toxicity values in U.S. EPA Region 5 *Ecological Data Quality Levels (EDQL) Database* (PRC 1995). The database contains media-specific EDQLs for the RCRA Appendix IX constituents (40 CFR Part 264). The EDQLs represent conservative media concentrations

protective of media receptors and wildlife that might be exposed through food chains based in these media. Available studies were obtained and toxicity values were verified. UFs were applied depending on study endpoint and available information.

Original studies were obtained, where possible, and prioritized based on criteria listed in Chapter 5. Uncertainty factors were applied, as appropriate, based on criteria (discussed in Chapter 5) to develop *TRV* values. For COPCs without toxicity data, the *TRV* for a surrogate COPC was adopted. If an appropriate surrogate *TRV* was not available, no *TRV* value was identified. Generally, review of toxicity data available in the scientific literature indicates that limited *TRVs* are available for organic compounds; while *TRVs* for metals are available.

**Soil Invertebrate TRVs** The soil invertebrate *TRVs* listed in Table E-6 are based on bulk soil exposures. Available soil invertebrate toxicity values from the scientific literature were used to develop *TRVs* for these receptors. Soil invertebrate toxicity values were first identified from the following secondary sources:

1. Studies cited in *Toxicological Benchmarks for Potential Contaminants of Concern for Effects on Soil and Litter Invertebrates and Heterotrophic Process* (Will and Suter II 1995a). Available studies were obtained and toxicity values were verified. UFs were applied depending on study endpoint and available information.
2. Scientific literature was searched for toxicity values for outstanding compounds. Relevant studies were obtained, toxicity values were verified, and UFs were applied as described.

Original studies were obtained, where possible, and prioritized based on criteria listed in Chapter 5. Uncertainty factors were applied, as appropriate, based on criteria to develop *TRVs*. If no toxicity value was available for a COPC, the *TRV* for a surrogate COPC was adopted.

## **E-2.0 TRVs FOR WILDLIFE MEASUREMENT RECEPTORS**

*TRV* values for wildlife measurement receptors are listed in Tables E-7 (mammals) and E-8 (birds). *TRVs* were not developed for each avian and mammalian measurement receptor in the seven example food webs because of the paucity of species-specific data. Rather, U.S. EPA OSW focused on identifying a set of avian *TRVs* and a set of mammalian *TRVs* for the classes of compounds listed in Section 2.3. U.S. EPA OSW assumed that, among the literature reviewed for a particular guild, the lowest available toxicity value across orders in class Aves and across orders in class Mammalia would provide a conservative estimate of toxicity. Available mammalian and avian toxicity values from the scientific literature were used to develop *TRVs* for these receptors. Also, as previously noted, *TRV* values were not identified for amphibians and reptiles because of the paucity of toxicological information on these receptors. Wildlife measurement receptors *TRV* values were first identified from the following secondary sources:

1. Toxicity values compiled in *Toxicological Benchmarks for Wildlife: 1996 Revision* (Sample, Opresko, and Suter 1996).
2. Toxicity values listed in the Terretox database of U.S. EPA's *ECOTOXicology Database System* (U.S. EPA 1996b) were screened to identify studies potentially meeting the criteria listed in Chapter 5.

Original studies were compiled, where possible, and reviewed to verify their accuracy based on criteria listed in Chapter 5. In many cases, best scientific judgement was used to screen out studies with poor experimental design (see Chapter 5). Uncertainty factors were applied, as appropriate, to develop *TRVs* based on criteria presented in Chapter 5.

**Conversions** Some avian and mammalian toxicity data are expressed in terms of compound concentration in the food of the test organism. To convert to daily dose, it is necessary to determine the exposure duration and organism body weight. If the study does not report this information, the results should not be used to compute a *TRV*. If information on exposure duration and organism body weight is available, dietary concentration can be computed to dose using the following generic equation:

$$DD = \frac{C \cdot IR}{BW} \quad \text{Equation E-2}$$

where

|           |   |                                                 |
|-----------|---|-------------------------------------------------|
| <i>DD</i> | = | COPC dose (mg COPC/kg BW/day)                   |
| <i>C</i>  | = | Concentration of COPC in diet (mg COPC/kg food) |
| <i>IR</i> | = | Food ingestion rate (kg/day)                    |
| <i>BW</i> | = | Test organism body weight (kg)                  |

Calculated using Great Lakes Water Quality Initiative Tier II methodology.                                                                                                                                                                                                                                                                                                                                                       |
| Cadmium                               | Chronic criterion                  | 0.0022 (dissolved) | Not applicable                  | 0.0022           | U.S. EPA (1999). Value expressed as a function of water hardness and calculated as follows: $TRV = \exp(m_c[\ln(\text{hardness})] + b_c)$ where $m_c = 0.7852$ and $b_c = -2.715$ . Criterion was converted to dissolved concentration using the following conversion factor: $1.101672 - [(\ln \text{hardness})(0.041838)]$ . A assumed hardness of 100 mg/L and a conversion from mg/L to $\mu\text{g/L}$ were used to calculate the displayed value. |
| Chromium (hexavalent)                 | Chronic criterion                  | 0.011              | Not applicable                  | 0.011            | U.S. EPA (1999).                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Copper                                | Chronic criterion                  | 0.009 (dissolved)  | Not applicable                  | 0.009            | U.S. EPA (1999). Value expressed as a function of water hardness and calculated as follows: $TRV = \exp(m_c[\ln(\text{hardness})] + b_c)$ where $m_c = 0.8545$ and $b_c = -1.702$ . Criterion was converted to dissolved concentration using a conversion factor of 0.960. A assumed hardness of 100 mg/L and a conversion from mg/L to $\mu\text{g/L}$ were used to calculate the displayed value.                                                     |

**TABLE E-1**  
**FRESHWATER TOXICITY REFERENCE VALUES**

(Page 5 of 8)

| Compound          | Toxicity Value                     |                    | Uncertainty Factor <sup>b</sup> | TRV <sup>c</sup> | Reference and Notes <sup>d</sup>                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------|--------------------|---------------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | Duration and Endpoint <sup>a</sup> | Concentration      |                                 |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Total Cyanide     | Chronic criterion                  | 0.0052             | Not applicable                  | 0.0052           | U.S. EPA (1999). This value is expressed as mg free cyanide (as CN)/L.                                                                                                                                                                                                                                                                                                                                                                                |
| Lead              | Chronic criterion                  | 0.0025 (dissolved) | Not applicable                  | 0.0025           | U.S. EPA (1999). Value expressed as a function of water hardness and calculated as follows: $TRV = \exp(m_c[\ln(\text{hardness})] + b_c)$ where $m_c = 1.273$ and $b_c = -4.705$ . Criterion was converted to dissolved concentration using the following conversion factor: $1.46203 - [(\ln \text{hardness})(0.145712)]$ . A assumed hardness of 100 mg/L and a conversion from mg/L to $\mu\text{g/L}$ were used to calculate the displayed value. |
| Mercuric chloride | Chronic criterion                  | 0.00077            | Not applicable                  | 0.00077          | U.S. EPA (1999). This value was from data for inorganic mercury (II).                                                                                                                                                                                                                                                                                                                                                                                 |
| Methyl mercury    | Tier II SCV                        | 0.0000028          | Not applicable                  | 0.0000028        | Suter and Tsao (1996). Calculated using Great Lakes Water Quality Initiative Tier II methodology.                                                                                                                                                                                                                                                                                                                                                     |
| Nickel            | Chronic criterion                  | 0.052 (dissolved)  | Not applicable                  | 0.052            | U.S. EPA (1999). Value expressed as a function of water hardness and calculated as follows: $TRV = \exp(m_c[\ln(\text{hardness})] + b_c)$ where $m_c = 0.8460$ and $b_c = 0.0584$ . Criterion was converted to dissolved concentration using a conversion factor of 0.997. A assumed hardness of 100 mg/L and a conversion from mg/L to $\mu\text{g/L}$ were used to calculate the displayed value.                                                   |
| Selenium          | Chronic criterion                  | 0.005              | Not applicable                  | 0.005            | U.S. EPA (1999)                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Silver            | Proposed chronic criterion         | 0.00012            | Not applicable                  | 0.00012          | U.S. EPA (1987)                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**TABLE E-1**  
**FRESHWATER TOXICITY REFERENCE VALUES**

(Page 6 of 8)

| Compound | Toxicity Value                     |                   | Uncertainty Factor <sup>b</sup> | TRV <sup>c</sup> | Reference and Notes <sup>d</sup>                                                                                                                                                                                                                                                                                                                                                                   |
|----------|------------------------------------|-------------------|---------------------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | Duration and Endpoint <sup>a</sup> | Concentration     |                                 |                  |                                                                                                                                                                                                                                                                                                                                                                                                    |
| Zinc     | Chronic criterion                  | 0.118 (dissolved) | Not applicable                  | 0.118            | U.S. EPA (1999). Value expressed as a function of water hardness and calculated as follows: $TRV = \exp(m_c[\ln(\text{hardness})] + b_c)$ where $m_c = 0.8473$ and $b_c = 0.884$ . Criterion was converted to dissolved concentration using a conversion factor of 0.986. A assumed hardness of 100 mg/L and a conversion from mg/L to $\mu\text{g/L}$ were used to calculate the displayed value. |

Notes:

- a The duration of exposure is defined as chronic if it represents about 10 percent or more of the test animals lifetime expectancy. Acute exposures represent single exposures or multiple exposures occurring within a short time. For evaluating exposure duration, the following general guidelines were used. For invertebrates and other lower trophic level aquatic biota: (1) chronic duration lasted for 7 or more days, (2) subchronic duration lasted from 3 to 6 days, and (3) acute duration lasted 2 days or less. For fish: (1) chronic duration lasted for more than 90 days, (2) subchronic duration lasted from 14 to 90 days, and (3) acute duration lasted less than 2 weeks.
- b Uncertainty factors are used to extrapolate a toxicity value to a chronic NOAEL TRV. See Chapter 5 (Section 5.4) of the SLERAP for a discussion of the use of uncertainty factors.
- c TRV was calculated by multiplying the toxicity value with the uncertainty factor.
- d The references refer to the source of the toxicity value. Complete reference citations are provided below.
- e Best scientific judgment used to identify uncertainty factor. See Chapter 5 (Section 5.4.1.2) for a discussion the use of best scientific judgement. Factors evaluated include test duration, ecological relevance of endpoint, experimental design, and availability of toxicity data.
- f TRVs for metals are based on the dissolved metal concentration. According to U.S. EPA (1993) policy, concentrations of dissolved metal more closely approximate the bioavailable fraction of metal in the water column.

TABLE E-2

## MARINE/ESTUARINE SURFACE WATER TOXICITY REFERENCE VALUES

(Page 1 of 8)

| Compound                                       | Toxicity Value                     |               | Uncertainty Factor <sup>b</sup> | Toxicity Reference Value <sup>c</sup> | Reference and Notes <sup>d</sup>                                                                                                                                                                                                                       |
|------------------------------------------------|------------------------------------|---------------|---------------------------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                | Duration and Endpoint <sup>a</sup> | Concentration |                                 |                                       |                                                                                                                                                                                                                                                        |
| Polychlorinated dibenzo-p-dioxins (μg/L)       |                                    |               |                                 |                                       |                                                                                                                                                                                                                                                        |
| 2,3,7,8-TCDD                                   | LOEC                               | 0.000038      | 0.1                             | 0.0000038                             | No saltwater data were available, therefore, corresponding freshwater toxicity value was used (rainbow trout, <i>Oncorhynchus mykiss</i> ) from Mehrle et al. (1988). 2,3,4,5-TCDD toxicity value used.                                                |
| Polynuclear aromatic hydrocarbons (PAH) (μg/L) |                                    |               |                                 |                                       |                                                                                                                                                                                                                                                        |
| Total high molecular weight (HMW) PAHs         | Acute LC50                         | >50           | 0.01 <sup>e</sup>               | 0.5                                   | Rossi and Neff (1978) evaluated toxicity of three HMW (three or more aromatic rings) PAHs to the polychaete, <i>Neanthes arenaceodentata</i> . LC50 of each HMW PAH exceeded 50 μg/L. This TRV should be used if assessing the risk of total HMW PAHs. |
| Benzo(a)pyrene                                 | Acute LC50                         | >50           | 0.01 <sup>e</sup>               | 0.5                                   | Rossi and Neff (1978). Toxicity value for polychaete ( <i>N. arenaceodentata</i> ).                                                                                                                                                                    |
| Benzo(a)anthracene                             | Acute LC50                         | >50           | 0.01 <sup>e</sup>               | 0.5                                   | Toxicity value not available. TRV for benzo(a)pyrene used as surrogate.                                                                                                                                                                                |
| Benzo(b)fluoranthene                           | Acute LC50                         | >50           | 0.01 <sup>e</sup>               | 0.5                                   | Toxicity value not available. TRV for benzo(a)pyrene used as surrogate.                                                                                                                                                                                |
| Benzo(k)fluoranthene                           | Acute LC50                         | >50           | 0.01 <sup>e</sup>               | 0.5                                   | Toxicity value not available. TRV for benzo(a)pyrene used as surrogate.                                                                                                                                                                                |
| Chrysene                                       | Acute LC50                         | >50           | 0.01 <sup>e</sup>               | 0.5                                   | Rossi and Neff (1978). Toxicity of several PAHs was evaluated. LC50 of each individual HMW PAH exceeded 50 μg/L.                                                                                                                                       |
| Dibenz(a,h)anthracene                          | Acute LC50                         | >50           | 0.01 <sup>e</sup>               | 0.5                                   | Rossi and Neff (1978). Toxicity of several PAHs was evaluated. LC50 of individual HMW PAHs exceeded 50 μg/L.                                                                                                                                           |
| Indeno(1,2,3-cd)pyrene                         | Acute LC50                         | >50           | 0.01 <sup>e</sup>               | 0.5                                   | Toxicity value not available. TRV for benzo(a)pyrene used as surrogate.                                                                                                                                                                                |
| Polychlorinated biphenyls (PCB) (μg/L)         |                                    |               |                                 |                                       |                                                                                                                                                                                                                                                        |

## TABLE E-2

### MARINE/ESTUARINE SURFACE WATER TOXICITY REFERENCE VALUES

(Page 6 of 8)

---

Notes:

- a The duration of exposure is defined as chronic if it represents about 10 percent or more of the test animals lifetime expectancy. Acute exposures represent single exposures or multiple exposures occurring within a short time. For evaluating exposure duration, the following general guidelines were used. For invertebrates and other lower trophic level aquatic biota: (1) chronic duration lasted for 7 or more days, (2) subchronic duration lasted from 3 to 6 days, and (3) acute duration lasted 2 days or less. For fish: (1) chronic duration lasted for more than 90 days, (2) subchronic duration lasted from 14 to 90 days, and (3) acute duration lasted less than 2 weeks.
- b Uncertainty factors are used to extrapolate a toxicity value to a chronic NOAEL TRV. See Chapter 5 (Section 5.4) of the SLERAP for a discussion of the use of uncertainty factors.
- c TRV was calculated by multiplying the toxicity value with the uncertainty factor.
- d The references refer to the source of the toxicity value. Complete reference citations are provided at the end of this appendix.
- e Best scientific judgment used to identify uncertainty factor. See Chapter 5 (Section 5.4.1.2) for a discussion of the use of best scientific judgement. Factors evaluated include test duration, ecological relevance of endpoint, experimental design, and availability of toxicity data.

|       |   |                                                                      |
|-------|---|----------------------------------------------------------------------|
| EC50  | = | Effective concentration for 50 percent of the test organisms.        |
| FCV   | = | Final Chronic Values                                                 |
| HMV   | = | High molecular weight                                                |
| LC50  | = | Lethal concentration for 50 percent of the test organisms.           |
| LC100 | = | Lethal concentration for 100 percent of the test organisms.          |
| LOEC  | = | Lowest Observed Effect Concentration                                 |
| LOEL  | = | Lowest Observed Effect Level                                         |
| LT50  | = | Lethal threshold concentration for 50 percent of the test organisms. |
| NOAEL | = | No Observed Adverse Effect Level                                     |

| Zinc              | Not applicable              | Not applicable                     | 110                           | TRV is an ERL value calculated by Ingersoll et al. (1996) based on 28-day <i>H. azteca</i> toxicity tests.                                                                                     |

**TABLE E-3**

**FRESHWATER SEDIMENT TOXICITY REFERENCE VALUES**

**(Page 6 of 7)**

---

Notes:

- a Toxicity reference values are in units of micrograms per kilogram ( $\mu\text{g/kg}$ ) and milligrams per kilograms ( $\text{mg/kg}$ ) for organic and inorganic constituents, respectively.
- b Values are in units of liters per kilogram ( $\text{L/kg}$ ).  $K_{oc}$  = Organic carbon normalized sorption coefficient. References and equations used to calculate  $K_{oc}$  values are provided in Appendix A.
- c The references refer to the study from which the TRV was identified. Complete reference citations are provided below.
- d Freshwater sediment TRV calculated with the following equation:

$$\text{Freshwater sediment TRV} = \text{Freshwater TRV (Table E-1)} * K_{oc} * f_{oc,bs}$$

where,

$K_{oc}$  = organic carbon partition coefficient, and

$f_{oc,bs}$  = fraction of organic carbon in bed sediment, assumed to be 4 percent = 0.04.

$K_{oc}$  values discussed in Appendix A.

**REFERENCES**

Default TRVs for sediments in freshwater habitats were identified from the three sets of freshwater toxicity values presented below. While some compound-specific freshwater sediment toxicity information is available in the scientific literature, available toxicity values were not used because of the complexity in understanding the role of naturally-occurring sediment features (such as grain size, ammonia, sulfide, soil type, and organic carbon content) in toxicity to benthic invertebrates. Among these sets of value, the lowest available toxicity value for a particular compound was adopted as the TRV. In many cases, a default TRV was calculated from the corresponding freshwater TRV using EPA's equilibrium partitioning approach, assuming a 4 percent organic carbon content.

## TABLE E-4

### MARINE/ESTUARINE SEDIMENT TOXICITY REFERENCE VALUES

(Page 7 of 8)

---

#### Notes:

- a Sediment TRVs are in units of micrograms per kilogram ( $\mu\text{g/kg}$ ) and milligrams per kilograms ( $\text{mg/kg}$ ) for organic and inorganic constituents, respectively.
- b Values are in units of liters per kilogram ( $\text{L/kg}$ ).  $K_{\text{oc}}$  = Organic carbon normalized sorption coefficient. References and equations used to calculate values are provided in Appendix A.
- c The references refer to the study or studies from which the endpoint and concentrations were identified. Complete reference citations are provided below.
- d Sediment TRV calculated with the following equation:

$$\text{Sediment TRV} = \text{Marine/estuarine surface water TRV (Table E-2)} * K_{\text{oc}} * f_{\text{oc,bs}}$$

where,

$K_{\text{oc}}$  = organic carbon partition coefficient, and

$f_{\text{oc,bs}}$  = fraction of organic carbon in bed sediment, assumed to be 1 percent = 0.01.

$K_{\text{oc}}$  values are discussed in Appendix A.

|      |   |                          |
|------|---|--------------------------|
| EqP  | = | Equilibrium Partitioning |
| ERL  | = | Effects Range-Low        |
| HMW  | = | High molecular weight    |
| LEL  | = | Lowest Effect Level      |
| NOEL | = | No Observed Effect Level |
| TRV  | = | Toxicity Reference Value |

## TABLE E-4

### MARINE/ESTUARINE SEDIMENT TOXICITY REFERENCE VALUES

(Page 8 of 8)

#### REFERENCES

Default TRVs for sediments in marine and estuarine habitats were identified from several sets of toxicity values (standards, benchmarks, and guidelines) presented below. While some compound-specific marine/estuarine sediment toxicity information is available in the scientific literature, available toxicity values were not used because of the complexity in understanding the role of naturally-occurring sediment features (such as grain size, ammonia, sulfide, soil type, and organic carbon content) in toxicity to benthic invertebrates. Among these sets of value, the lowest available toxicity value for a particular compound was adopted as the TRV. In many cases, a default TRV was calculated from the corresponding freshwater TRV using EPA's equilibrium partitioning approach, assuming a 4 percent organic carbon content.

**TABLE E-5**  
**TERRESTRIAL PLANT TOXICITY REFERENCE VALUES**

**(Page 6 of 15)**

---

Notes:

- a To evaluate exposure duration, the following general guidelines were used: Chronic duration represents exposures occurring about 10 or more days, including exposure during a critical life stage, such as germination and shoot development. Subchronic duration generally lasts 2 days through several days, however a sensitive life stage is not exposed. Acute duration generally includes exposures occurring 0 to 2 days.
- b Uncertainty factors are used to extrapolate a toxicity value to a chronic NOAEL TRV. See Chapter 5 (Section 5.4) of the SLERAP for a discussion on the use of uncertainty factors.
- c TRV was calculated by multiplying the toxicity value with the uncertainty factor.
- d The references refer to the source of the toxicity value. Complete reference citations are provided below.
- e Best scientific judgment was used to identify uncertainty factor. See Chapter 5 (Section 5.4.1.2) for a discussion on the use of best scientific judgement. Factors evaluated include test duration, ecological relevance of endpoint, and experimental design.

|       |   |                                                               |
|-------|---|---------------------------------------------------------------|
| EC50  | = | Effective concentration for 50 percent of the test organisms. |
| HWC   | = | High molecular weight                                         |
| LOAEL | = | Lowest Observed Adverse Effects Level                         |
| NOAEL | = | No Observed Adverse Effects Level                             |
| NOEC  | = | No Observed Effects Concentration                             |
| TRV   | = | Toxicity Reference Value                                      |

## TABLE E-5

### TERRESTRIAL PLANT TOXICITY REFERENCE VALUES

(Page 7 of 15)

#### REFERENCES

Efroymson, Will, Suter II, and Wooten (1997) provides a comprehensive review of ecologically-relevant terrestrial plant toxicity information. This source was reviewed to identify studies to develop TRVs for terrestrial plant. Based on the information presented, one or more references were obtained and reviewed to identify compound-specific toxicity values. For some compounds, the available information identified a single study meeting the requirements for a TRV, as discussed in Chapter 5 (Section 5.4) of the SLERAP. In most cases, each reference was obtained and reviewed to identify a single toxicity value to develop a TRV for each compound. In a few cases where a primary study could not be obtained, a toxicity value is based on a secondary source. As noted below, additional compendia were reviewed to identify toxicity studies to review. For compounds not discussed in Efroymson, Will, Suter II, and Wooten (1997), the scientific literature was searched, and relevant studies were obtained and reviewed. The references reviewed are listed below. The study selected for the TRV is highlighted in bold.

| Zinc              | Chronic (56-day) NOEC for cocoon production                       | Earthworm ( <i>Eisenia foetida</i> ) | 199           | Not applicable                  | 199              | Spurgeon et al. (1994)                                                                                                                                                                                                          |

## TABLE E-6

### SOIL INVERTEBRATE TOXICITY REFERENCE VALUES

(Page 6 of 12)

---

Notes:

- a - duration, the following general guidelines were used: Chronic duration represents exposures occurring about 10 or more days, including exposure during a critical life stage encompassing a sensitive endpoint. Subchronic duration generally lasts 2 days through several days, however a sensitive life stage is not exposed. Acute duration generally includes exposures from 0 to 2 days.
- b Uncertainty factors are used to extrapolate a toxicity value to a chronic NOAEL TRV. See Chapter 5 (Section 5.4) of the SLERAP for a discussion on the use of uncertainty factors.
- c TRV was calculated by multiplying the toxicity value with the uncertainty factor.
- d The references refer to the source of the toxicity value. Complete reference citations are provided below.
- e Best scientific judgment used to identify uncertainty factor. See Chapter 5 (Section 5.4.1.2) for a discussion on the use of best scientific judgement. Factors evaluated include test duration, ecological relevance of measured effect, experimental design, and availability of toxicity data.

|       |   |                                                           |
|-------|---|-----------------------------------------------------------|
| HMW   | = | High molecular weight                                     |
| LC50  | = | Concentration lethal to 50 percent of the test organisms. |
| NOAEL | = | No Observed Adverse Effects Level                         |
| NOEC  | = | No Observed Effects Level                                 |
| UF    | = | Uncertainty Factor                                        |
| TRV   | = | Toxicity Reference Value                                  |

## TABLE E-6

### SOIL INVERTEBRATE TOXICITY REFERENCE VALUES

(Page 7 of 12)

#### REFERENCES

Efroymson, Will, and Suter II (1997) provides a comprehensive review of ecologically-relevant soil invertebrate toxicity information. This source was reviewed to identify studies to develop TRVs for invertebrates. Effects of compounds on microbial communities were not considered. Based on the information presented, one or more references were obtained and reviewed to identify compound-specific toxicity values. For some compounds, the available information identified a single study meeting the requirements for a TRV, as discussed in Section 5.4. In most cases, each reference was obtained and reviewed to identify a single toxicity value to develop a TRV for each compound. In a few cases where a primary study could not be obtained, a toxicity value is based on a secondary source. As noted below, additional compendia were reviewed to identify toxicity studies to review. For compounds not discussed in Efroymson, Will, and Suter II (1997), the scientific literature was searched, and relevant studies were obtained and reviewed. The references reviewed are listed below. The study selected for the TRV is highlighted in bold.

|          | Duration and Endpoint <sup>a</sup>               | Test Organism | Dose <sup>b</sup> | Uncertainty Factor <sup>c</sup> |        |                                  |
| Thallium | Subchronic (60 days) LOAEL (testicular function) | Rat           | 1.31              | 0.01 <sup>h</sup>               | 0.0131 | Formigli et al. (1986)           |
| Zinc     | Subchronic (13 weeks) NOAEL                      | Mouse         | 104               | 0.1                             | 10.4   | Maita et al. (1981)              |

## Notes:

- a The duration of exposure is defined as chronic if it represents about 10 percent or more of the test animal's lifetime expectancy. Acute exposures represent single exposure or multiple exposures occurring within about two weeks or less. Subchronic exposures are defined as multiple exposures occurring for less than 10 percent of the test animal's lifetime expectancy but more than 2 weeks.
- b Reported values, which were dose in food or diet, were converted to dose based on body weight and intake rate using Opresko, Sample, and Suter 1996.
- c Uncertainty factors are used to extrapolate a toxicity value to a chronic NOAEL TRV. See Chapter 5 (Section 5.4) for a discussion on the use of uncertainty factors. The TRV was calculated by multiplying the toxicity value by the uncertainty factor.
- d The references refer to the study or studies from which the endpoint and doses were identified. Complete reference citations are provided at the end of this table.
- e Best scientific judgement used to identify uncertainty factor. See Chapter 5 (Section 5.4.1.2) for a discussion of the use of best scientific judgement. Factors evaluated include test duration, ecological relevance of endpoint, experimental design, and availability of toxicity data.

HMW = High molecular weight  
 LD50 = Lethal dose to 50 percent of the test organisms.  
 LOAEL = Lowest Observed Adverse Effect Level  
 NOAEL = No Observed Adverse Effect Level  
 TRV = Toxicity Reference Value

## TABLE E-7

### MAMMAL TOXICITY REFERENCE VALUES

(Page 6 of 15)

#### REFERENCES

Sample, Opresko, and Suter II (1996) provides a comprehensive review of ecologically-relevant mammal toxicity information. This source was reviewed to identify studies to develop TRVs for mammals. Based on the information presented, one or more references were obtained and reviewed to identify compound-specific toxicity values. For some compounds, the available information identified a single study meeting the requirements for a TRV, as discussed in Section 5.4. In most cases, each reference was obtained and reviewed to identify a single toxicity value to develop a TRV for each compound. In a few cases where a primary study could not be obtained, a toxicity value is based on a secondary source. As noted below, additional compendia were reviewed to identify toxicity studies to review. For compounds not discussed in Sample, Opresko, and Suter II (1996), the scientific literature was searched, and relevant studies were obtained and reviewed. The references reviewed are listed below. The study selected for the TRV is highlighted in bold.

#### *Polychlorinated dibenzo(p)dioxins*

**Murray, F.J., F.A. Smith, K.D. Nitschke, C.G. Humiston, R.J. Kociba, and B.A. Schwetz. 1979. "Three-Generation Reproduction Study of Rats Given 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) in the Diet." *Toxicology and Applied Pharmacology*. Volume 50. Pages 241-252.**

## TABLE E-8

### BIRD TOXICITY REFERENCE VALUES

(Page 6 of 13)

---

Notes:

- a The duration of exposure is defined as chronic if it represents about 10 percent or more of the test animal's lifetime expectancy. Acute exposures represent single exposure or multiple exposures occurring within about two weeks or less. Subchronic exposures are defined as multiple exposures occurring for less than 10 percent of the test animal's lifetime expectancy but more than 2 weeks.
- b Reported value which were dose in diet or water were converted to dose based on body weight and intake rate using Opresko, Sample, and Suter (1996).
- c Uncertainty factors are used to extrapolate a reported toxicity value to a chronic NOAEL TRV. See Chapter 5 (Section 5.4) of the SLERAP for a discussion on the use of uncertainty factors. The TRV was calculated by multiplying the toxicity value by the uncertainty factor. A "not applicable" uncertainty factor is equivalent to a value equal to 1.0.
- d The references refer to the study from which the endpoint and doses were identified. Complete reference citations are provided below.
- e Best scientific judgement used to identify uncertainty factor. See Chapter 5 (Section 5.4.1.2) for a discussion on the use of best scientific judgement. Factors evaluated include test duration, ecological relevance of endpoint, experimental design, and availability of toxicity data.

|       |   |                                                           |
|-------|---|-----------------------------------------------------------|
| HMW   | = | High molecular weight                                     |
| LOAEL | = | Lowest Observed Adverse Effect Level                      |
| LD50  | = | Concentration lethal to 50 percent of the test organisms. |
| NOAEL | = | No Observed Adverse Effect Level                          |
| TRV   | = | Toxicity Reference Value                                  |

## TABLE E-8

### BIRD TOXICITY REFERENCE VALUES

(Page 7 of 13)

#### REFERENCES

Sample, Opresko, and Suter II (1996) provides a comprehensive review of bird toxicity information. This source was reviewed to identify studies to develop TRVs for birds. Based on the information presented, one or more references were obtained and reviewed to identify compound-specific toxicity values. For some compounds, the available information identified a single study meeting the requirements for a TRV, as discussed in Chapter 5 (Section 5.4) of the SLERAP. In most cases, each reference was obtained and reviewed to identify a single toxicity value to develop a TRV for each compound. As noted below, additional compendia were reviewed to identify toxicity studies to review. In a few cases where a primary study could not be obtained, a toxicity value is based on a secondary source. For compounds not discussed in Sample, Opresko, and Suter II (1996), the scientific literature was searched, and relevant studies were obtained and reviewed. The references reviewed are listed below. The study selected for the TRV is highlighted in bold.

#### *Polychlorinated dibenzo(p)dioxins*

**Nosek, J.A., S.R. Craven, J.R. Sullivan, S.S. Hurley, and R.E. Peterson. 1992. "Toxicity and Reproductive Effects of 2,3,7,8-Tetrachlorodibenzo-p-dioxin in Ring-Necked Pheasant Hens." *Journal of Toxicology and Environmental Health*. Volume 35. Pages 187-198.**

U.S. EPA. 1993. *Interim Report on Data and Methods for Assessment of 2,3,7,8-Tetrachlorodibenzo-p-dioxin Risks to Aquatic Life and Associated Wildlife*. EPA/600/R-93/055. Office of Research and Development. Washington, D.C. March. This report identified the two studies listed below.

Greig, J.B., G. Jones, W.H. Butler, and J.M. Barnes. 1973. "Toxic Effects of 2,3,7,8-Tetrachlorodibenzo-p-dioxins. *Food and Cosmetics Toxicology*. Volume 11. Pages 585-595.

Hudson, R., R. Tucker, and M. Haegle. 1984. *Handbook of Toxicity of Pesticides to Wildlife*. Second Ed. U.S. Fish and Wildlife, Resources Publication No. 153. Washington, D.C.

#### *Benzo(a)pyrene*

**Brunström, B., D. Broman, and C. Näf. 1991. "Toxicity and EROD-Inducing Potency of 24 Polycyclic Aromatic Hydrocarbons (PAHs) in Chick Embryos." *Archives of Toxicology*. Volume 65. Pages 485-489.**

#### *Benzo(a)anthracene*

TABLE F-1-1

**COPC CONCENTRATIONS IN TERRESTRIAL PLANTS  
FOR TERRESTRIAL FOOD WEBS**

(Page 1 of 2)

**Description**

This equation calculates the COPC concentration in plants due to: (1)  $Pd$  - wet and dry deposition of COPCs onto plant surfaces, (2)  $Pv$  - uptake of vapor phase COPCs onto plant surfaces, (3)  $Pr$  uptake of COPCs from soil through plant roots. Uncertainties associated with the use of this equation include the following:

Uncertainties introduced by this variable include the following:

- (1) Some of the variables in the equations in Tables B-3-7, B-3-8, and B-3-9—including  $Cs$ ,  $Cyv$ ,  $Q$ ,  $Dydp$ , and  $Dywp$ —are COPC- and site-specific. Uncertainties associated with these variables are site-specific.
- (2) In the equation in Table B-3-7, uncertainties associated with other variables include the following:  $F_w$  (values for organic compounds estimated on the basis of the behavior of polystyrene microspheres),  $Rp$  (estimated on the basis of a generalized empirical relationship),  $kp$  (estimation process does not consider chemical degradation). All of these uncertainties contribute to the overall uncertainty associated with  $C_{TP}$ .

**Equation**

$$C_{TP} = ( Pd + Pv + Pr )$$

| Variable | Description                              | Units         | Value |
|----------|------------------------------------------|---------------|-------|
| $C_{TP}$ | COPC concentration in terrestrial plants | mg COPC/kg WW |       |

TABLE F-1-1

**COPC CONCENTRATIONS IN TERRESTRIAL PLANTS  
FOR TERRESTRIAL FOOD WEBS**

(Page 2 of 2)

| Variable  | Description                                      | Units         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|--------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Pd</i> | Plant concentration due to direct deposition     | mg COPC/kg WW | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is calculated with the equation in Table B-3-1. This variable represents the COPC concentration in plants due to wet and dry deposition of COPCs onto plant surfaces. The limitations and uncertainty introduced in calculating this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) Variables <math>Q</math>, <math>Dydp</math>, and <math>Dywp</math> are COPC- and site-specific. Uncertainties associated with these variables are site-specific.</li> <li>(2) In calculating the variable <math>Fw</math>, values of <math>r</math> assumed for most organic compounds—based on the behavior of insoluble polystyrene microspheres tagged with radionuclides—may accurately represent the behavior of organic compounds under site-specific conditions.</li> <li>(3) The empirical relationship used to calculate the variable <math>Rp</math>, and the empirical constant for use in the relationship, may not accurately represent site-specific plant types.</li> <li>(4) The recommended procedure for calculating the variable <math>kp</math> does not consider chemical degradation processes. This conservative approach contributes to the possible overestimation of plant concentrations.</li> </ol> |
| <i>Pv</i> | Plant concentration due to air-to-plant transfer | mg COPC/kg WW | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is calculated with the equation in Table B-3-2.</p> <p>Uncertainties associated with the use of this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The algorithm used to calculate values for the variable <math>F_v</math> assumes a default value for the parameter <math>S_T</math> (Whitby's average surface area of particulates [aerosols]) of background plus local sources, rather than an <math>S_T</math> value for urban sources. If a specific site is located in an urban area, the use of the latter <math>S_T</math> value may be more appropriate. The <math>S_T</math> value for urban sources is about one order of magnitude greater than that for background plus local sources and would result in a lower <math>F_v</math> value; however, the <math>F_v</math> value is likely to be only a few percent lower.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                   |
| <i>Pr</i> | Plant concentration due to root uptake           | mg COPC/kg WW | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is calculated with the equation in Table B-3-3. <math>C_s</math> is the COPC concentration in soil due to deposition. This variable is calculated using emissions data, ISCST3 air dispersion and deposition model, and soil fate and transport equations (presented in Appendix B).</p> <p>Uncertainties associated with the use of this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The availability of site-specific information, such as meteorological data, will affect the accuracy of <math>C_s</math> estimates.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <p>This equation calculates the COPC concentration in herbivorous mammals through the ingestion of plants, soil, and water in the forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainty introduced in calculating this variable include the following:</p> <p>(1) Variables: <math>C_{TP}</math>, <math>C_S</math>, and <math>C_{wctot}</math> are COPC- and site-specific. Uncertainties associated with these variables are site-specific.</p> <p>(2) Variables: <math>BCF_{TP-HM}</math>, <math>BCF_{S-HM}</math> and <math>BCF_{W-HM}</math> are based on biotransfer factors for beef cattle (<math>Ba_{beef}</math>), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations in site-specific herbivorous mammals.</p> |                                           |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Variable      | Description                                                         | Units                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $BCF_{TP-HM}$ | Bioconcentration factor for terrestrial plant-to-herbivorous mammal | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg WW)] | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in herbivorous mammals through dietary exposure. <math>BCF_{TP-HM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| $P_{TP}$      | Proportion of terrestrial plant in diet that is contaminated        | unitless                                          | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| $F_{TP}$      | Fraction of diet comprised of terrestrial plants                    | unitless                                          | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of terrestrial plants. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |

TABLE F-1-2

**COPC CONCENTRATIONS IN HERBIVOROUS MAMMALS  
IN FOREST, SHORTGRASS PRAIRIE, TALLGRASS PRAIRIE,  
AND SHRUB/SCRUB FOOD WEBS**

(Page 3 of 4)

| Variable     | Description                                            | Units                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_s$        | COPC concentration in soil                             | mg COPC /kg<br>DW soil                                             | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC- and site-specific, and should be calculated using the equation in Table B-1-1. This variable is calculated using emissions data, ISCST3 air dispersion and deposition model, and soil fate and transport equations (presented in Appendix B). <math>C_s</math> is expressed on a dry weight basis.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) For soluble COPCs, leaching might lead to movement to below 1 centimeter in untilled soils, resulting a greater mixing depth. This uncertainty may overestimate <math>C_s</math>.</li> <li>(2) Deposition to hard surfaces may result in dust residues that have negligible dilution (as a result of potential mixing with <i>in situ</i> materials) in comparison to that of other residues. This uncertainty may underestimate <math>C_s</math>.</li> <li>(3) Modeled soil concentrations may not accurately represent site-specific conditions. As a result, the actual COPC concentration in soil may be under- or overestimated to an unknown degree.</li> </ol> |
| $BCF_{S-HM}$ | Bioconcentration factor for soil-to-herbivorous mammal | unitless [(mg<br>COPC/kg FW<br>tissue)/(mg<br>COPC/kg DW<br>soil)] | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in herbivorous mammals through soil exposure. <math>BCF_{S-HM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| $P_s$        | Proportion of ingested soil that is contaminated       | unitless                                                           | <p style="text-align: center;"><b>0 to 1<br/>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of soil ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for a screening level risk assessment when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated soil ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of soil ingested that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                             |

| Variable     | Description                                                      | Units                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|------------------------------------------------------------------|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$  | Total COPC concentration in water column                         | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup><br>water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same media, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $BCF_{w-HM}$ | Bioconcentration factor for water-to-herbivorous mammal pathways | unitless [(mg COPC/kg FW tissue)/(mg COPC/L water)]       | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in herbivorous mammals through indirect water exposure (total water body concentration). <math>BCF_{w-HM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

TABLE F-1-3

**COPC CONCENTRATIONS IN INVERTEBRATES  
IN FOREST, SHORTGRASS PRAIRIE, TALLGRASS PRAIRIE, AND SHRUB/SCRUB FOOD WEBS**

(Page 1 of 2)

| Variable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Description                                       | Units         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_w$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Proportion of ingested water that is contaminated | unitless      | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This OSW variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA recommend that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated will likely be overestimated.</p> |
| <p style="text-align: center;"><b>Description</b></p> <p>This equation calculates the COPC concentration in invertebrates through exposure to soil in the forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainty introduced in calculating this variable include the following:</p> <p>(1) <math>C_s</math> values are COPC- and site-specific. Uncertainties associated with these variables are site specific.</p> <p>(2) <math>BCF_{S-INV}</math> values are intended to represent “generic invertebrate species”, and therefore may over- or under-estimate exposure for site-specific organisms.</p> |                                                   |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <p style="text-align: center;"><b>Equation</b></p> $C_{INV} = C_s \cdot BCF_{S-INV}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                   |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

TABLE F-1-3

**COPC CONCENTRATIONS IN INVERTEBRATES  
IN FOREST, SHORTGRASS PRAIRIE, TALLGRASS PRAIRIE, AND SHRUB/SCRUB FOOD WEBS**

(Page 2 of 2)

| Variable      | Description                                      | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_s$         | COPC concentration in soil                       | mg COPC /kg DW soil                                    | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC- and site-specific, and should be calculated using the equation in Table B-1-1. This variable is calculated using emissions data, ISCST3 air dispersion and deposition model, and soil fate and transport equations (presented in Appendix B). <math>C_s</math> is expressed on a dry weight basis.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) For soluble COPCs, leaching might lead to movement to below 1 centimeter in untilled soils, resulting a greater mixing depth. This uncertainty may overestimate <math>C_s</math>.</li> <li>(2) Deposition to hard surfaces may result in dust residues that have negligible dilution (as a result of potential mixing with <i>in situ</i> materials) in comparison to that of other residues. This uncertainty may underestimate <math>C_s</math>.</li> <li>(3) Modeled soil concentrations may not accurately represent site-specific conditions. As a result, the actual COPC concentration in soil may be under- or overestimated to an unknown degree.</li> </ol> |
| $BCF_{S-INV}$ | Bioconcentration factor for soil-to-invertebrate | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg DW soil)] | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site- and species-specific, and is provided in Appendix C.</p> <p>The following uncertainties are associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The COPC specific <math>BCF_{S-INV}</math> values may not accurately represent site-specific soil conditions which could influence the bioavailability of COPCs, therefore over- or under-estimating <math>C_{INV}</math> to an unknown degree.</li> <li>(2) The data set used to calculate <math>BCF_{S-INV}</math> is based on a limited number of test organism. The uncertainty associated with calculating concentrations using <math>BCF_{S-INV}</math> in site-specific organisms is unknown and may over- or under-estimate <math>C_{INV}</math>.</li> </ol>                                                                                                                                                                                                                                                                                                                               |

| <p>This equation calculates the COPC concentration in herbivorous birds through the ingestion of plants, soil, and water in the forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainty introduced in calculating this variable include the following:</p> <p>(1) Variables: <math>C_{TP}</math>, <math>C_S</math>, and <math>C_{wctot}</math> are COPC- and site-specific. Uncertainties associated with these variables are site specific.</p> <p>(2) Variables: <math>BCF_{TP-HB}</math>, <math>BCF_{S-HB}</math>, and <math>BCF_{W-HB}</math> are calculated based on biotransfer factors for chicken (<math>Ba_{chicken}</math>), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations in site-specific herbivorous birds.</p> <p>(3) The use of a single <math>Ba_{chicken}</math> value for each COPC may not accurately reflect site-specific conditions. The default values may under- or overestimate <math>C_{HB}</math>.</p> |                                          |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| $BCF_{TP-HB}$ | Bioconcentration factor for plant-to-herbivorous bird        | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg WW)] | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, habitat- and receptor-specific, and is calculated using the following equation to compute the COPC concentration in herbivorous birds through dietary exposure. <math>BCF_{TP-HB}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| $P_{TP}$      | Proportion of terrestrial plant in diet that is contaminated | unitless                                          | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| $F_{TP}$      | Fraction of diet comprised of terrestrial plants             | unitless                                          | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of terrestrial plants. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces significant uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces significant uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |

| Variable     | Description                                           | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|-------------------------------------------------------|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$  | Total COPC concentration in water column              | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same media, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $BCF_{w-HB}$ | Bioconcentration factor for water-to-herbivorous bird | unitless [(mg COPC/kg FW tissue)/(mg COPC/L water)]    | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in herbivorous birds through indirect exposure to water. <math>BCF_{w-HB}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $P_w$        | Proportion of ingested water that is contaminated     | unitless                                               | <p style="text-align: center;"><b>0 to 1<br/>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor homerange, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

TABLE F-1-5

**COPC CONCENTRATIONS IN OMNIVOROUS MAMMALS  
IN FOREST, TALLGRASS PRAIRIE, SHORTGRASS PRAIRIE, AND SHRUB/SCRUB FOOD WEBS**

(Page 1 of 9)

**Description**

This equation calculates the COPC concentration in omnivorous mammals through ingestion of plants, soil, and water in the forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainty introduced in calculating this variable include the following:

- (1) Variables  $C_S$ , and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables are site specific.
- (2) Variables:  $BCF_{W-OM}$  and  $BCF_{S-OM}$  are calculated based on biotransfer factors for beef cattle ( $Ba_{beef}$ ), and receptor specific ingestion rates, and may introduce significant uncertainty when used to compute concentrations in site-specific omnivorous mammals.
- (3)  $FCMs$  are COPC- and site-specific and may introduce uncertainty when applied to terrestrial environments to account for COPC bioaccumulation between trophic level (see Chapter 5 for further discussion).

**Equation**

$$C_{OM} = (C_{INV} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{INV} \cdot F_{INV}) + (C_{TP} \cdot BCF_{TP-OM} \cdot P_{TP} \cdot F_{TP}) + (C_{HM} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{HM} \cdot F_{HM})$$

$$+ (C_{HB} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{HB} \cdot F_{HB}) + (C_S \cdot BCF_{S-OM} \cdot P_S) + (C_{wctot} \cdot BCF_{W-OM} \cdot P_W)$$

| Variable | Description                              | Units                | Value |
|----------|------------------------------------------|----------------------|-------|
| $C_{OM}$ | COPC concentration in omnivorous mammals | mg COPC/kg FW tissue |       |

| Variable | Description                                                  | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|--------------------------------------------------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_{TP}$ | Proportion of terrestrial plant in diet that is contaminated | unitless             | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| $F_{TP}$ | Fraction of diet comprised of terrestrial plants             | unitless             | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of terrestrial plants. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |
| $C_{HM}$ | COPC concentration in herbivorous mammals                    | mg COPC/kg FW tissue | <p style="text-align: center;"><b>Varies (calculated - Table F-1-2)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-2. Uncertainties associated with this variable include:</p> <p>(1) Variables: <math>C_{TP}</math>, <math>C_S</math>, and <math>C_{wctot}</math> are COPC- and site-specific.</p> <p>(2) Variables: <math>BCF_{TP-HM}</math>, <math>BCF_{S-HM}</math>, and <math>BCF_{W-HM}</math> are based on biotransfer factors for beef cattle (<math>Ba_{beef}</math>), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations in site-specific mammals.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**COPC CONCENTRATIONS IN OMNIVOROUS MAMMALS  
IN FOREST, TALLGRASS PRAIRIE, SHORTGRASS PRAIRIE, AND SHRUB/SCRUB FOOD WEBS**

(Page 6 of 9)

| Variable | Description                                                  | Units    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------|--------------------------------------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_{HB}$ | Proportion of herbivorous birds in diet that is contaminated | unitless | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| $F_{HB}$ | Fraction of diet comprised of herbivorous birds              | unitless | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of herbivorous birds. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |

| Variable     | Description                                           | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|-------------------------------------------------------|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_s$        | COPC concentration in soil                            | mg COPC /kg DW soil                                    | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC- and site-specific, and should be calculated using the equation in Table B-1-1. <math>C_s</math> is expressed on a dry weight basis.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) For soluble COPCs, leaching might lead to movement to below 1 centimeter in untilled soils, resulting a greater mixing depth. This uncertainty may overestimate <math>C_s</math>.</li> <li>(2) Deposition to hard surfaces may result in dust residues that have negligible dilution (as a result of potential mixing with <i>in situ</i> materials) in comparison to that of other residues. This uncertainty may underestimate <math>C_s</math>.</li> <li>(3) Modeled soil concentrations may not accurately represent site-specific conditions. As a result, the actual COPC concentration in soil may be under- or overestimated to an unknown degree.</li> </ol> |
| $BCF_{s-OM}$ | Bioconcentration factor for soil-to-omnivorous mammal | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg DW soil)] | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in omnivorous mammals through indirect soil exposure. <math>BCF_{s-OM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| $P_s$        | Proportion of ingested soil that is contaminated      | unitless                                               | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of soil ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for a screening level risk assessment when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated soil ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of soil ingested that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                       |

| Variable     | Description                                                     | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|-----------------------------------------------------------------|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$  | Total COPC concentration in water column                        | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same media, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $BCF_{w-OM}$ | Bioconcentration factor for water-to-omnivorous mammal pathways | unitless [(mg COPC/kg FW tissue)/(mg COPC/L water)]    | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in herbivorous mammals through indirect water exposure (total water body concentration). <math>BCF_{w-OM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $P_w$        | Proportion of ingested water that is contaminated               | unitless                                               | <p style="text-align: center;"><b>0 to 1<br/>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. TABLE F-1-6

**COPC CONCENTRATIONS IN OMNIVOROUS BIRDS  
IN FOREST, TALLGRASS PRAIRIE, SHORTGRASS PRAIRIE, AND SHRUB/SCRUB FOOD WEBS**

(Page 1 of 7)

**Description**

This equation calculates the COPC concentration in omnivorous birds through the ingestion of plants, soil, and water in the forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainty introduced in calculating this variable include the following:

- (1) Variables  $C_S$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables are site specific.
- (2) Variables:  $BCF_{W-OB}$  and  $BCF_{S-OB}$  are calculated based on biotransfer factors for chicken ( $Ba_{Chicken}$ ), and receptor specific ingestion rates, and may introduce uncertainty when used to compute concentrations in site-specific omnivorous birds.
- (3)  $FCMs$  are COPC- and site-specific and may introduce uncertainty when applied to terrestrial environments to account for COPC bioaccumulation between trophic (see Chapter 5).

**Equation**

$$C_{OB} = (C_{INV} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{INV} \cdot F_{INV}) + (C_{TP} \cdot BCF_{TP-OM} \cdot P_{TP} \cdot F_{TP}) \\ + (C_S \cdot BCF_{S-OB} \cdot P_S) + (C_{wctot} \cdot BCF_{W-OB} \cdot P_W)$$

IN FOREST, TALLGRASS PRAIRIE, SHORTGRASS PRAIRIE, AND SHRUB/SCRUB FOOD WEBS**

(Page 4 of 7)

| Variable | Description                                                  | Units    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|--------------------------------------------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_{TP}$ | Proportion of terrestrial plant in diet that is contaminated | unitless | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommend that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $F_{TP}$ | Fraction of diet comprised of terrestrial plants             | unitless | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of terrestrial plants. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |

TABLE F-1-7

**COPC CONCENTRATIONS IN AQUATIC VEGETATION IN THE FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 1 of 2)

**Description**

This equation calculates the COPC concentration in aquatic vegetation through direct sediment exposure in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:

- (1)  $C_{sed}$  values are COPC- and site-specific. Uncertainties associated with these variables are site specific.
- (2)  $BCF_{W-AV}$  values are intended to represent “generic benthic invertebrate species”, and therefore may over- or under-estimate exposure when applied to site-specific organisms.

**Equation**

$$C_{AV} = C_{sed} \cdot BCF_{S-AV}$$

TABLE F-1-8

**COPC CONCENTRATIONS IN ALGAE IN THE FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND  
SALTMARSH FOOD WEBS**

(Page 1 of 2)

**Description**

This equation calculates the COPC concentration in algae through direct water exposure in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:

- (1)  $C_{dw}$  values are COPC- and site-specific. Uncertainties associated with these variables are site specific.
- (2)  $BCF_{W-AL}$  values are intended to represent “generic algae species”, and therefore may over- or under-estimate exposure when applied to site-specific organisms.

**Equation**

$$C_{AL} = C_{dw} \cdot BCF_{W-AL}$$

| Variable | Description                            | Units               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| $C_{dw}$ | Dissolved phase water<br>concentration | mg COPC/<br>L water | <p align="center"><b>Varies</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-18.</p> <p>Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) The variables in the equation in Table B-2-18 are site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{dw}</math>. The degree of uncertainty associated with TSS is expected to be relatively small, because information regarding reasonable site-specific values for this variable is generally available or can be easily measured.</li> <li>(2) The uncertainty associated with the variables <math>C_{wctot}</math> and <math>Kd_{sw}</math> is dependent on estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using different OC content values may be significant in specific cases.</li> </ol> |

TABLE F-1-9

**COPC CONCENTRATIONS IN HERBIVOROUS MAMMALS  
IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 1 of 5)

**Description**

This equation calculates the COPC concentration in aquatic herbivorous mammals through the ingestion of plants, sediment, and water in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:

- (1) Variables:  $C_{AV}$ ,  $C_{sed}$ , and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables are site specific.
- (2) Variables:  $BCF_{TP-HM}$ ,  $BCF_{BS-HM}$ , and  $BCF_{W-HM}$  are based on biotransfer factors for beef cattle ( $Ba_{beef}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations in site-specific herbivorous mammals.
- (3) The use of single  $Ba_{beef}$  value for each COPC may not accurately reflect site-specific conditions, and may under- or overestimate  $C_{HM}$ .

**Equation**

$$C_{HM} = (C_{AV} \cdot BCF_{HM} \cdot P_{AV} \cdot F_{AV}) + (C_{AL} \cdot BCF_{HM} \cdot P_{AL} \cdot F_{AL}) + (C_{sed} \cdot BCF_{BS-HM} \cdot P_{BS}) + (C_{wctot} \cdot BCF_{W-HM} \cdot P_W)$$

| Variable | Description                                                   | Units         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------|---------------------------------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_{AV}$ | Proportion of aquatic vegetation in diet that is contaminated | unitless      | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p style="padding-left: 40px;">The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| $F_{AV}$ | Fraction of diet comprised of aquatic vegetation              | unitless      | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic vegetation. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |
| $C_{AL}$ | COPC concentration in algae                                   | mg COPC/kg WW | <p style="text-align: center;"><b>Varies (calculated - Table F-1-8)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-8. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) <math>C_{dw}</math> values are COPC- and site-specific.</li> <li>(2) <math>BCF_{W-AL}</math> values are intended to represent “generic algae species”, and therefore may over- or under-estimate exposure when applied to site-specific species.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Variable      | Description                                                            | Units                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{sed}$     | COPC concentration in bed sediment                                     | mg COPC/kg DW sediment                                     | <p style="text-align: center;"><b>Varies (calculated - Table B-2-19)</b></p> <p>This equation calculates the concentration of contaminants sorbed to bed sediments. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The default variable values recommended for use in the equation in Table B-2-19 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with variables <math>\theta_{bs}</math>, <math>C_{sed}</math>, <math>w_{totc}</math>, and <math>d_{bs}</math> is expected to be limited either because the probable ranges for these variables are narrow or because information allowing reasonable estimates is generally available.</li> <li>(2) Uncertainties associated with variables <math>f_{bs}</math>, <math>C_{wtot}</math> and <math>Kd_{bs}</math> are largely associated with the use of default OC content values in their calculation. The uncertainty may be significant in specific instances, because OC content is known to vary widely in different locations in the same medium. This variable is site-specific.</li> </ol> |
| $BCF_{BS-HM}$ | Bioconcentration factor for bed sediment-to-aquatic herbivorous mammal | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg DW sediment)] | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic herbivorous mammals through indirect sediment exposure. <math>BCF_{BS-HM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| $P_{BS}$      | Proportion of ingested bed sediment that is contaminated               | unitless                                                   | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of sediment ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for a screening level risk assessment when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated soil ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of soil ingested that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                  |

TABLE F-1-9

**COPC CONCENTRATIONS IN HERBIVOROUS MAMMALS  
IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALT MARSH FOOD WEBS**

(Page 5 of 5)

| Variable     | Description                                                              | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$  | Total COPC concentration in water column                                 | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same media, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $BCF_{w-HM}$ | Bioconcentration factor for water-to-aquatic herbivorous mammal pathways | unitless [(mg COPC/kg FW tissue)/(mg COPC/L water)]    | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic herbivorous mammals through indirect water exposure. <math>BCF_{w-HM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| $P_w$        | Proportion of ingested water that is contaminated                        | unitless                                               | <p style="text-align: center;"><b>0 to 1<br/>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <p>This equation calculates the COPC concentration in aquatic herbivorous birds through ingestion of contaminated plants, sediment, and water in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:</p> <p>(1) Variables: <math>C_{AV}</math>, <math>C_{sed}</math>, and <math>C_{wctot}</math> are COPC- and site-specific. Uncertainties associated with these variables are site specific.</p> <p>(2) Variables: <math>BCF_{AV-HB}</math>, <math>BCF_{BS-HB}</math>, and <math>BCF_{W-HB}</math> are calculated based on biotransfer factors for chicken (<math>Ba_{chicken}</math>), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations for site-specific herbivorous birds.</p> <p>(3) The use of single <math>Ba_{chicken}</math> value for each COPC may not accurately reflect site-specific conditions; and may under- or overestimate <math>C_{HB}</math>.</p> |                                                                              |                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**COPC CONCENTRATIONS IN HERBIVOROUS BIRDS  
IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 2 of 5)

| Variable | Description                                                   | Units         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|---------------------------------------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_{AV}$ | Proportion of aquatic vegetation in diet that is contaminated | unitless      | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| $F_{AV}$ | Fraction of diet comprised of aquatic vegetation              | unitless      | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic vegetation. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |
| $C_{AL}$ | COPC concentration in algae                                   | mg COPC/kg WW | <p style="text-align: center;"><b>Varies (calculated - Table F-1-8)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-8. Uncertainties associated with this variable include:</p> <p>(1) <math>C_{dw}</math> values are COPC- and site-specific.</p> <p>(2) <math>BCF_{W-AL}</math> values are intended to represent “generic algae species”, and therefore may over- or under-estimate exposure when applied to site-specific species.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Variable      | Description                                                          | Units                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|----------------------------------------------------------------------|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{sed}$     | COPC concentration in bed sediment                                   | mg COPC/kg DW sediment                                     | <p><b>Varies (calculated - Table B-2-19)</b></p> <p>This equation calculates the concentration of COPCs in bed sediments. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The default variable values recommended for use in the equation in Table B-2-19 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with variables <math>\theta_{bs}</math>, <math>C_{sed}</math>, <math>w_{totc}</math>, and <math>d_{bs}</math> is expected to be limited either because the probable ranges for these variables are narrow or because information allowing reasonable estimates is generally available.</li> <li>(2) Uncertainties associated with variables <math>f_{bs}</math>, <math>C_{wtof}</math> and <math>Kd_{bs}</math> are largely associated with the use of default OC content values in their calculation. The uncertainty may be significant in specific instances, because OC content is known to vary widely in different locations in the same medium. This variable is site-specific.</li> </ol> |
| $BCF_{BS-HB}$ | Bioconcentration factor for bed sediment-to-aquatic herbivorous bird | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg DW sediment)] | <p><b>Varies</b></p> <p>This variable is COPC-, site-, habitat- and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic herbivorous birds through indirect sediment exposure. <math>BCF_{BS-HB}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| $P_{BS}$      | Proportion of ingested bed sediment that is contaminated             | unitless                                                   | <p><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of soil ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for a screening level risk assessment when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated soil ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of soil ingested that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                        |

| Variable     | Description                                                   | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|---------------------------------------------------------------|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$  | Total COPC concentration in water column                      | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $BCF_{w-HB}$ | Bioconcentration factor for water-to-aquatic herbivorous bird | unitless [(mg COPC/kg FW tissue)/(mg COPC/L water)]    | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic herbivorous birds through indirect exposure to water. <math>BCF_{w-HB}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| $P_w$        | Proportion of ingested water that is contaminated             | unitless                                               | <p style="text-align: center;"><b>0 to 1<br/>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <p>This equation calculates the COPC concentration in benthic invertebrates through direct exposure to benthic sediment in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:</p> <p>(1) <math>C_{sed}</math> values are COPC- and site-specific. Uncertainties associated with these variables are site specific.</p> <p>(2) <math>BCF_{BS-BI}</math> values are intended to represent “generic benthic invertebrate species”, and therefore may over- or under-estimate exposure when applied to site-specific organisms.</p> |                                             |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| $C_{sed}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | COPC concentration in bed sediment          | mg COPC/kg DW sediment | <p><b>Varies (calculated - Table B-2-19)</b></p> <p>This equation calculates the concentration of COPCs in bed sediments. Uncertainties associated with this equation include the following:</p> <p>(1) The default variable values recommended for use in the equation in Table B-2-19 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with variables <math>\theta_{bs}</math>, <math>C_{sed}</math>, <math>d_{wc}</math>, and <math>d_{bs}</math> is expected to be limited either because the probable ranges for these variables are narrow or because information allowing reasonable estimates is generally available.</p> <p>(2) Uncertainties associated with variables <math>f_{bs}</math>, <math>C_{wtot}</math> and <math>Kd_{bs}</math> are largely associated with the use of default <i>OC</i> content values in their calculation. The uncertainty may be significant in specific instances, because <i>OC</i> content is known to vary widely in different locations in the same medium. This variable is site-specific.</p> |

| <p>This equation calculates the COPC concentration in water invertebrates through direct water exposure in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:</p> <p>(1) <math>C_{dw}</math> values are COPC- and site-specific. Uncertainties associated with these variables are site specific.</p> <p>(2) <math>BCF_{WI}</math> values are intended to represent “generic water invertebrate species”, and therefore may over- or under-estimate exposure when applied to site-specific organisms.</p> |                                           |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| $C_{dw}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Dissolved phase water concentration       | mg COPC/L water      | <p><b>Varies (calculated - Table B-2-18)</b></p> <p>This variable is COPC- and site-specific. This equation calculates the concentration of COPC dissolved in the water column. Uncertainties associated with this equation include the following:</p> <p>(1) The variables in the equation in Table B-2-18 are site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{dw}</math>. The degree of uncertainty associated with <math>TSS</math> is expected to be relatively small, because information regarding reasonable site-specific values for this variable are generally available or it can be easily measured. On the other hand, the uncertainty associated with the variables <math>C_{wctor}</math> and <math>Kd_{sw}</math> is associated with estimates of <math>OC</math> content. Because <math>OC</math> content values can vary widely for different locations in the same medium, using default <math>OC</math> values may result in significant uncertainty in specific cases.</p> |

| <p>This equation calculates the COPC concentration in herbivorous/planktivorous fish through ingestion of contaminated food and direct water exposure in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:</p> <p>(1) <math>C_{dw}</math> values are COPC- and site-specific. Uncertainties associated with these variables are site specific.</p> <p>(2) The data set used to calculate <math>BCF_f</math> is based on a limited number of test organisms and therefore may over- or under-estimate exposure when applied to site-specific organisms.</p> |                                                          |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| $C_{dw}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Dissolved phase water concentration                      | mg COPC/L water      | <p><b>Varies (calculated - Table B-2-18)</b></p> <p>This variable is COPC- and site-specific. This equation calculates the concentration of COPC dissolved in the water column. Uncertainties associated with this equation include the following:</p> <p>(1) The variables in the equation in Table B-2-18 are site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{dw}</math>. The degree of uncertainty associated with TSS is expected to be relatively small, because information regarding reasonable site-specific values for this variable are generally available or it can be easily measured. On the other hand, the uncertainty associated with the variables <math>C_{wctot}</math> and <math>Kd_{sw}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, using default OC values may result in significant uncertainty in specific cases.</p> |

(Page 1 of 10)

**Description**

This equation calculates the COPC concentration in aquatic omnivorous mammals through ingestion of plants, sediment, and water in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:

- (1) Variables:  $C_{sed}$ , and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables are site specific.
- (2) Variables:  $BCF_{BS-OM}$ , and  $BCF_{W-OM}$  are based on biotransfer factors for beef cattle ( $Ba_{beef}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations in site-specific omnivorous mammals.

**Equation**

$$\begin{aligned}
 C_{OM} = & (C_{BI} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{BI} \cdot F_{BI}) + (C_{WI} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{WI} \cdot F_{WI}) + (C_{HM} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{HM} \cdot F_{HM}) \\
 & + (C_{HB} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{HB} \cdot F_{HB}) + (C_{AL} \cdot BCF_{AL-OM} \cdot P_{AL} \cdot F_{AL}) + (C_{AV} \cdot BCF_{AV-OM} \cdot P_{AV} \cdot F_{AV}) \\
 & + (C_{sed} \cdot BCF_{BS-OM} \cdot P_{BS}) + (C_{wctot} \cdot BCF_{W-OM} \cdot P_W)
 \end{aligned}$$

| Variable | Description                                                           | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|-----------------------------------------------------------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $F_{WT}$ | Fraction of diet comprised of water invertebrates                     | unitless             | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of water invertebrates. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |
| $C_{HM}$ | Concentration of COPC in herbivorous mammals                          | mg COPC/kg FW tissue | <p style="text-align: center;"><b>Varies (calculated - Table F-1-9)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-9. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Variables: <math>C_{AV}</math>, <math>C_{AL}</math>, <math>C_{sed}</math>, and <math>C_{wctot}</math> are COPC- and site-specific.</li> <li>(2) Variables: <math>BCF_{BS-HM}</math> and <math>BCF_{W-HM}</math> are based on biotransfer factors for beef cattle (<math>Ba_{beef}</math>), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations for site-specific herbivorous mammals.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $P_{HM}$ | Proportion of aquatic herbivorous mammal in diet that is contaminated | unitless             | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Variable      | Description                                            | Units                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|--------------------------------------------------------|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $F_{HB}$      | Fraction of diet comprised of herbivorous birds        | unitless                                          | <p><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic herbivorous birds. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |
| $C_{AL}$      | COPC concentration in algae                            | mg COPC/kg WW                                     | <p><b>Varies (calculated - Table F-1-8)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-8. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) <math>C_{dw}</math> values are COPC- and site-specific.</li> <li>(2) <math>BCF_{W-AL}</math> values are intended to represent “generic algae species”, and therefore may over- or under-estimate exposure when applied to site-specific species.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| $BCF_{AL-OM}$ | Bioconcentration factor for algae-to-omnivorous mammal | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg WW)] | <p><b>Varies</b></p> <p>This variable is COPC-, site-, habitat- and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic omnivorous mammals through indirect dietary exposure. <math>BCF_{AL-OM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Variable | Description                                                     | Units         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|-----------------------------------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_{AL}$ | Proportion of algae in diet that is contaminated                | unitless      | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| $F_{AL}$ | Fraction of diet comprised of algae                             | unitless      | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of algae. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |
| $C_{AV}$ | COPC concentration in aquatic vegetation ingested by the animal | mg COPC/kg WW | <p style="text-align: center;"><b>Varies (calculated - Table F-1-7)</b></p> <p>This variable is site- and COPC-specific; it is calculated using the equation in Table F-1-7. Uncertainties associated with this variable include:</p> <p>(1) <math>C_{sed}</math> values are COPC- and site-specific. Uncertainties associated with this variable may be significant, and should be summarized as part of each SLERA report.</p> <p>(2) <math>BCF_{BS-AV}</math> values are intended to represent “generic aquatic vegetation species”, and therefore may over- or under-estimate exposure when applied to site-specific vegetation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Variable      | Description                                                                 | Units                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $BCF_{AV-OM}$ | Bioconcentration factor for aquatic vegetation-to-aquatic omnivorous mammal | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg WW)] | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, habitat- and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic omnivorous mammals through indirect dietary exposure. <math>BCF_{AV-OM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $P_{AV}$      | Proportion of aquatic vegetation in diet that is contaminated               | unitless                                          | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| $F_{AV}$      | Fraction of diet comprised of aquatic vegetation                            | unitless                                          | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic vegetation. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |

| Variable      | Description                                                                    | Units                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------|------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{sed}$     | COPC concentration sorbed to bed sediment                                      | mg COPC/kg DW sediment                                     | <p style="text-align: center;"><b>Varies (calculated - Table B-2-19)</b></p> <p>This equation calculates the concentration of contaminants sorbed to bed sediments. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The default variable values recommended for use in the equation in Table B-2-19 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with default variable values is expected to be limited either because the probable ranges for these variables are narrow or because information allowing reasonable estimates is generally available.</li> <li>(2) Uncertainties associated with variables <math>f_{bs}</math>, <math>C_{wtot}</math> and <math>Kd_{bs}</math> are largely associated with the use of default OC content values in their calculation. The uncertainty may be significant in specific instances, because OC content is known to vary widely in different locations in the same medium. This variable is site-specific.</li> </ol> |
| $BCF_{BS-OM}$ | Bioconcentration factor for bed sediment-to-aquatic omnivorous mammal pathways | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg DW sediment)] | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic omnivorous mammals through indirect sediment exposure. <math>BCF_{BS-OM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| $P_{BS}$      | Portion of ingested bed sediment that is contaminated                          | unitless                                                   | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of soil ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for a screening level risk assessment when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated soil ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of soil ingested that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                     |

| Variable     | Description                                                    | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|----------------------------------------------------------------|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$  | Total COPC concentration in water column                       | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $BCF_{w-OM}$ | Bioconcentration factor for water-to-aquatic omnivorous mammal | unitless [(mg COPC/kg FW tissue)/(mg COPC/L water)]    | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic omnivorous mammals through indirect water exposure. <math>BCF_{w-OM}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| $P_w$        | Portion of ingested water that is contaminated                 | unitless                                               | <p style="text-align: center;"><b>0 to 1<br/>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor homerange, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

TABLE F-1-15

**COPC CONCENTRATIONS IN OMNIVOROUS BIRDS  
IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 1 of 9)

**Description**

This equation calculates the COPC concentration in aquatic omnivorous birds through ingestion of plants, sediment, and water in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:

- (1) Variables:  $C_{sed}$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables are site specific.
- (2) Variables:  $BCF_{BS-OB}$  and  $BCF_{W-OB}$  are calculated based on biotransfer factors for chicken ( $Ba_{chicken}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations for site-specific omnivorous birds.

**Equation**

$$C_{OB} = (C_{BI} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{BI} \cdot F_{BI}) + (C_{WI} \cdot \frac{FCM_{TL3}}{FCM_{TL2}} \cdot P_{WI} \cdot F_{WI}) + (C_{AV} \cdot BCF_{AV-OM} \cdot P_{AV} \cdot F_{AV}) \\ + (C_{AL} \cdot BCF_{AL-OM} \cdot P_{AL} \cdot F_{AL}) + (C_{sed} \cdot BCF_{BS-OB} \cdot P_{BS}) + (C_{wctot} \cdot BCF_{W-OB} \cdot P_W)$$

| Variable | Description                                 | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| $FCM_{TL3}$<br>$FCM_{TL2}$ | Food chain multiplier for trophic level 3 predator consuming trophic level 2 prey | unitless | <p><b>Varies</b></p> <p>This variable is COPC- and trophic level-specific and is provided in Chapter 5, Table 5-2. The following uncertainties are associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) <math>FCMs</math> do not account for metabolism, thus for COPCs with significant metabolism, concentrations may be over-estimated to an unknown degree.</li> <li>(2) The application of <math>FCMs</math> for computing concentration in terrestrial food webs may introduce uncertainty (see Chapter 5)</li> </ol> <p><math>FCMs</math> are obtained from the U.S. EPA 1995 "Great Lakes Water Quality Initiative Technical Support Document for the Procedure to Determine Bioaccumulation Factors."</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| $P_{BI}$                   | Proportion of benthic invertebrate in diet that is contaminated                   | unitless | <p><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| $F_{BI}$                   | Fraction of diet comprised of benthic invertebrates                               | unitless | <p><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of benthic invertebrates. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

| Variable      | Description                                                  | Units                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|--------------------------------------------------------------|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $F_{AV}$      | Fraction of diet comprised of aquatic vegetation             | unitless                                          | <p><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic vegetation. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |
| $C_{AL}$      | COPC concentration in algae                                  | mg COPC/kg WW                                     | <p><b>Varies (calculated - Table F-1-8)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-8. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) <math>C_{dw}</math> values are COPC- and site-specific.</li> <li>(2) <math>BCF_{W-AL}</math> values are intended to represent “generic algae species”, and therefore may over- or under-estimate exposure when applied to site-specific species.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $BCF_{AL-OB}$ | Bioconcentration factor for algae-to-aquatic omnivorous bird | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg WW)] | <p><b>Varies</b></p> <p>This variable is COPC-, site-, habitat- and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic omnivorous birds through indirect dietary exposure. <math>BCF_{AL-OB}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

TABLE F-1-15

**COPC CONCENTRATIONS IN OMNIVOROUS BIRDS  
IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 6 of 9)

| Variable | Description                                      | Units    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|--------------------------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_{AL}$ | Proportion of algae in diet that is contaminated | unitless | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommend that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| $F_{AL}$ | Fraction of diet comprised of algae              | unitless | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of algae. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |

**COPC CONCENTRATIONS IN OMNIVOROUS BIRDS  
IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 7 of 9)

| Variable      | Description                                                                  | Units                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|------------------------------------------------------------------------------|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{sed}$     | COPC concentration in bed sediment                                           | mg COPC/kg DW sediment                                     | <p style="text-align: center;"><b>Varies (calculated - Table B-2-19)</b></p> <p>This equation calculates the concentration of contaminants sorbed to bed sediments. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The default variable values recommended for use in the equation in Table B-2-19 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with default variable values is expected to be limited either because the probable ranges for these variables are narrow or because information allowing reasonable estimates is generally available.</li> <li>(2) Uncertainties associated with variables <math>f_{bs}</math>, <math>C_{wtot}</math> and <math>Kd_{bs}</math> are largely associated with the use of default OC content values in their calculation. The uncertainty may be significant in specific instances, because OC content is known to vary widely in different locations in the same medium. This variable is site-specific. It is the maximum COPC concentration in sediment in the assessment area and is computed from soil and surface water concentrations using the ISCST3 air dispersion and deposition model, and fate and transport equations presented in Chapter 3.</li> </ol> |
| $BCF_{BS-HB}$ | Bioconcentration factor for bed sediment-to-aquatic omnivorous bird pathways | unitless [(mg COPC/kg FW tissue)/(mg COPC/kg DW sediment)] | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, habitat- and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic herbivorous birds through indirect sediment exposure. <math>BCF_{BS-OB}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| $P_{BS}$      | Portion of ingested bed sediment that is contaminated                        | unitless                                                   | <p style="text-align: center;"><b>0 to 1<br/>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of soil ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for a screening level risk assessment when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated soil ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of soil ingested that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

TABLE F-1-15

**COPC CONCENTRATIONS IN OMNIVOROUS BIRDS  
IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 8 of 9)

| Variable     | Description                                                  | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|--------------------------------------------------------------|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$  | Total COPC concentration in water column                     | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $BCF_{w-OB}$ | Bioconcentration factor for water-to-aquatic omnivorous bird | unitless [(mg COPC/kg FW tissue)/(mg COPC/L water)]    | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC-, site-, and receptor-specific, and is calculated using the following equation to compute the COPC concentration in aquatic omnivorous birds through indirect exposure to water. <math>BCF_{w-OB}</math> values are provided in Appendix D.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| $P_w$        | Portion of ingested water that is contaminated               | unitless                                               | <p style="text-align: center;"><b>0 to 1<br/>Default: 1.0</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA OSW recommend that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor home range, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <p>This equation calculates the COPC concentration in omnivorous fish through ingestion of contaminated food and water exposure in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:</p> <p>(1) <math>C_{dw}</math> values are COPC- and site-specific.</p> <p>(2) The data set used to calculate <math>BCF_f</math> is based on a limited number of test organisms and therefore may over- or under-estimate exposure when representing site-specific organisms.</p> |                                       |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Equation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                       |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| $C_{dw}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Dissolved phase water concentration   | mg COPC/L water      | <p><b>Varies (calculated - Table B-2-18)</b></p> <p>This variable is COPC- and site-specific. This equation calculates the concentration of COPC dissolved in the water column. Uncertainties associated with this equation include the following:</p> <p>(1) The variables in the equation in Table B-2-18 are site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{dw}</math>. The degree of uncertainty associated with <math>TSS</math> is expected to be relatively small, because information regarding reasonable site-specific values for this variable are generally available or it can be easily measured. On the other hand, the uncertainty associated with the variables <math>C_{wctot}</math> and <math>Kd_{sw}</math> is associated with estimates of <math>OC</math> content. Because <math>OC</math> content values can vary widely for different locations in the same media, using default <math>OC</math> values may result in uncertainty in specific cases.</p> |

TABLE F-1-17

**COPC CONCENTRATIONS IN CARNIVOROUS FISH  
IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 1 of 3)

**Description**

This equation calculates the COPC concentration in carnivorous fish through ingestion of contaminated prey and water exposure in the freshwater/wetland, brackish/intermediate marsh, and saltmarsh food webs. The limitations and uncertainty introduced in calculating this variable include the following:

- (1)  $C_{dw}$  values are COPC- and site-specific.
- (2) The data set used to calculate  $BCF_f$  is based on a limited number of test organisms and therefore may over- or under-estimate exposure when representing site-specific organisms.

**Equation**

$$C_{CF} = C_{dw} \cdot BCF_f \cdot FCM_{TL4}$$

TABLE F-2-1

**COPC DOSE INGESTED TERMS IN HERBIVOROUS MAMMALS  
IN FOREST, SHORTGRASS PRAIRIE, TALLGRASS PRAIRIE, AND SHRUB/SCRUB FOOD WEBS**

(Page 1 of 4)

**Description**

This equation calculates the daily dose through exposure to contaminated food or prey, soil, and water in herbivorous mammals in upland forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_s$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables will be site specific.
- (2) Variables  $BCF_{S-HM}$  and  $BCF_{W-HM}$  are based on biotransfer factors for beef cattle ( $Ba_{beef}$ ), and receptor-specific ingestion rates, and therefore may introduce uncertainty when used to compute a daily dose for representative site-specific herbivorous mammals.

**Equation**

$$D_{HM} = (C_{TP} \cdot IR_{HM} \cdot P_{TP} \cdot F_{TP}) + (C_s \cdot IR_{S-HM} \cdot P_s) + (C_{wctot} \cdot IR_{W-HM} \cdot P_w)$$

| Variable | Description                                | Units             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Variable  | Description                                                  | Units           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|--------------------------------------------------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $IR_{HM}$ | Food ingestion rate of herbivorous mammal                    | kg WW/kg BW-day | <p style="text-align: center;"><b>Varies</b></p> <p>Food ingestion rates (<math>IR_{HM}</math>) are site-, receptor-, and habitat-specific and are provided in Chapter 5, Table 5-1.</p> <p>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight (U.S. EPA 1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| $P_{TP}$  | Proportion of terrestrial plant in diet that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $F_{TP}$  | Fraction of diet comprised of terrestrial plants             | unitless        | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of terrestrial plants. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |

| Variable    | Description                                       | Units           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$ | Total COPC concentration in water column          | mg COPC/L water | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>k_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same media, using default OC values may result in uncertainty in specific cases.</p> |
| $IR_{W-HM}$ | Water ingestion rate of herbivorous mammal        | L/kg BW-day     | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Water ingestion rates are strongly influenced by animal behavior and environmental factors and may over- or under- estimate <math>BCF_{W-HM}</math> to an unknown degree.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $P_w$       | Proportion of ingested water that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor homerange, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

TABLE F-2-2

**COPC DOSE INGESTED TERMS IN HERBIVOROUS BIRDS  
IN FOREST, SHRUB/SCRUB, SHORTGRASS PRAIRIE, AND TALLGRASS PRAIRIE FOOD WEBS**

(Page 1 of 5)

**Description**

This equation calculates the daily dose through exposure to contaminated food/prey, soil, and water in herbivorous birds in upland forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_s$ , and  $C_{HB}$  are COPC- and site-specific. Uncertainties associated with these variables will be site-specific.
- (2) Variables  $BCF_{S-HB}$ , and  $BCF_{W-HB}$  are based on biotransfer factors for chicken ( $Ba_{chicken}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute a daily dose representing site-specific herbivorous birds.

**Equation**

$$D_{HB} = (C_{TP} \cdot IR_{HB} \cdot P_{TP} \cdot F_{TP}) + (C_s \cdot IR_{S-HB} \cdot P_s) + (C_{wctot} \cdot IR_{W-HB} \cdot P_w)$$

| Variable | Description                                                        | Units         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------|--------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $D_{HB}$ | Dose COPC ingested for herbivorous birds                           | mg/kg BW-day  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| $C_{TP}$ | Concentration of COPC in terrestrial plants ingested by the animal | mg COPC/kg WW | <p><b>Varies</b></p> <p>This variable is site- and COPC-specific; it is calculated using the equation in Table F-1-1.</p> <p>Uncertainties introduced by this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) Some of the variables in the equations in Tables B-3-1, B-3-2, and B-3-3—including <math>C_s</math>, <math>C_{yv}</math>, <math>Q</math>, <math>Dydp</math>, and <math>Dywp</math>—are COPC- and site-specific. Uncertainties associated with these variables may be significant, and should be summarized as part of each SLERA report.</li> <li>(2) In the equation in Table B-3-1, uncertainties associated with other variables include the following: <math>F_w</math> (values for organic compounds estimated on the basis of the behavior of polystyrene microspheres), <math>Rp</math> (estimated on the basis of a generalized empirical relationship), and <math>kp</math> (estimation process does not consider chemical degradation). All of these uncertainties contribute to the overall uncertainty associated with <math>C_{TP}</math>.</li> </ol> |

| Variable  | Description                                               | Units           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|-----------------------------------------------------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $IR_{HB}$ | Food ingestion rate of herbivorous bird                   | kg WW/kg BW-day | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Chapter 5, Table 5-1. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</li> <li>(2) IR values may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| $P_{TP}$  | Proportion of terrestrial plant diet that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| $F_{TP}$  | Fraction of diet comprised of terrestrial plants          | unitless        | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of terrestrial plants. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

**COPC DOSE INGESTED TERMS IN HERBIVOROUS BIRDS  
IN FOREST, SHRUB/SCRUB, SHORTGRASS PRAIRIE, AND TALLGRASS PRAIRIE FOOD WEBS**

(Page 3 of 5)

| Variable    | Description                                      | Units                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|--------------------------------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_s$       | COPC soil concentration                          | mg COPC /kg<br>DW soil | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is COPC- and site-specific, and should be calculated using the equation in Table B-1-1. This variable is calculated from stack emissions using the ISCST3 air dispersion and deposition model and soil fate and transport equations presented in Appendix B. <math>C_s</math> is expressed on a dry weight basis.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) For soluble COPCs, leaching might lead to movement to below 1 centimeter in untilled soils, resulting a greater mixing depth. This uncertainty may overestimate <math>C_s</math> and <math>C_{sD}</math>.</li> <li>(2) Deposition to hard surfaces may result in dust residues that have negligible dilution (as a result of potential mixing with <i>in situ</i> materials) in comparison to that of other residues. This uncertainty may underestimate <math>C_s</math></li> <li>(3) Modeled soil concentrations may not accurately represent site-specific conditions. As a result, the actual COPC concentration in soil may be under- or overestimated to an unknown degree.</li> </ol> |
| $IR_{S-HB}$ | Soil ingestion rate for herbivorous bird         | kg DW/kg BW-<br>day    | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is site-, receptor-, and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) <math>IR_s</math> values may under- or over-estimate <math>BCF_s</math> when applied for site-specific organisms.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $P_s$       | Proportion of ingested soil that is contaminated | unitless               | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of soil ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for a screening level risk assessment when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated soil ingested by species depends on site-specific information, receptor homerange, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of soil ingested that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                      |

| Variable    | Description                                       | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|---------------------------------------------------|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$ | Total COPC concentration in water column          | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-16)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-16. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-16. are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $IR_{W-HB}$ | Water ingestion rate for herbivorous bird         | kg WW/kg BW-day                                        | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Water ingestion rates are strongly influenced by animal behavior and environmental factors and may over- or under- estimate <math>BCF_{W-HB}</math> to an unknown degree.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| $P_w$       | Proportion of ingested water that is contaminated | unitless                                               | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor homerange, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <p>This equation calculates the daily dose through exposure to contaminated food/prey, soil, and water in omnivorous mammals in upland forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainties introduced in calculating this variable include the following:</p> <p>(1) Variables <math>C_s</math> and <math>C_{wctot}</math> are COPC- and site-specific. Uncertainties associated with these variables will be site-specific.</p> <p>(2) Variables <math>BCF_{S-OM}</math>, and <math>BCF_{W-OM}</math> are based on biotransfer factors for beef cattle (<math>Ba_{beef}</math>), and receptor-specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific omnivorous mammals.</p> |                                              |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| $C_{HM}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Concentration of COPC in herbivorous mammals | mg COPC/kg FW tissue | <p><b>Varies (calculated - Table F-1-2)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-9. Uncertainties associated with this variable include:</p> <p>(1) Variables <math>C_{sed}</math> and <math>C_{wctot}</math> are COPC- and site-specific.</p> <p>(2) Variables <math>BCF_{S-HM}</math> and <math>BCF_{W-HM}</math> are based on biotransfer factors for beef cattle (<math>Ba_{beef}</math>), and receptor-specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations for site-specific herbivorous mammals.</p> |

TABLE F-2-3

**COPC DOSE INGESTED TERMS IN OMNIVOROUS MAMMALS  
IN FOREST, SHRUB/SCRUB, SHORTGRASS PRAIRIE, AND TALLGRASS PRAIRIE FOOD WEBS**

(Page 2 of 8)

| Variable  | Description                                                   | Units           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|---------------------------------------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $IR_{OM}$ | Food ingestion rate of omnivorous mammal                      | kg WW/kg BW-day | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Chapter 5, Table 5-1. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</li> <li>(2) <math>IR</math> values may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol>             |
| $P_{HM}$  | Proportion of herbivorous mammal in diet that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommend that a default value of 1.0 be used for all food types when site specific information is not available. Uncertainties associated with this variable include:</p> <p style="padding-left: 40px;">The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                     |
| $F_{HM}$  | Fraction of diet comprised of herbivorous mammals             | unitless        | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of herbivorous mammals. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. The application of an equal diet is further discussed in section Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of herbivorous mammals depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. Therefore a default value of 100 percent for the exclusive diet, may over-estimate dietary exposure.</li> </ol> |

| Variable    | Description                                       | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|---------------------------------------------------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$ | Total COPC concentration in water column          | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may result because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same media, using default OC values may result in uncertainty in specific cases.</p> |
| $IR_{w-OM}$ | Water ingestion rate for omnivorous mammal        | L/kg DW-day                                            | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Water ingestion rates are influenced by animal behavior and environmental factors and may over- or under-estimate <math>BCF_{w-OM}</math> to an unknown degree.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| $P_w$       | Proportion of ingested water that is contaminated | unitless                                               | <p style="text-align: center;"><b>0 to 1<br/>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor homerange, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

TABLE F-2-4

**COPC DOSE INGESTED TERMS IN OMNIVOROUS BIRDS  
IN FOREST, SHRUB/SCRUB, TALLGRASS PRAIRIE, AND SHORTGRASS PRAIRIE FOOD WEBS**

(Page 1 of 6)

**Description**

This equation calculates the daily dose through exposure to contaminated food/prey, soil, and water in omnivorous birds in upland forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_s$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables will be site specific.
- (2) Variables  $BCF_{S-OB}$  and  $BCF_{W-OB}$  are based on biotransfer factors for chicken ( $Ba_{chicken}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute a daily dose for site-specific omnivorous birds.

**Equation**

$$D_{OB} = (C_{INV} \cdot IR_{OB} \cdot P_{INV} \cdot F_{INV}) + (C_{TP} \cdot IR_{OB} \cdot P_{TP} \cdot F_{TP}) + (C_s \cdot IR_{S-OB} \cdot P_S) + (C_{wctot} \cdot IR_{W-OB} \cdot P_W)$$

| Variable    | Description                                       | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|---------------------------------------------------|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$ | Total COPC concentration in water column          | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values and may be significant in specific instances. Uncertainties associated with the variable <math>L_T</math> and <math>K_{wt}</math> may also be significant because of many variable-specific uncertainties.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same media, default OC values will result in uncertainty in specific cases.</p> |
| $IR_{W-OB}$ | Water ingestion rate for omnivorous bird          | L/kg BW-day                                            | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Water ingestion rates are influenced by animal behavior and environmental factors and may over- or under-estimate <math>BCF_{W-OB}</math> to an unknown degree.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| $P_w$       | Proportion of ingested water that is contaminated | unitless                                               | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used when site specific information is not available.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated water ingested by species depends on site-specific information, receptor homerange, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of ingested water that is contaminated may be overestimated.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

TABLE F-2-5

**COPC DOSE INGESTED TERMS IN CARNIVOROUS MAMMALS  
IN FOREST, SHORTGRASS PRAIRIE, TALLGRASS PRAIRIE, AND SHRUB/SCRUB FOOD WEBS**

(Page 1 of 8)

**Description**

This equation calculates the daily dose through exposure to food/prey, soil, and water in carnivorous mammal in upland forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_s$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables will be site-specific
- (2) Variables  $BCF_{S-CM}$ , and  $BCF_{W-CM}$  are based on biotransfer factors for beef cattle ( $Ba_{beef}$ ), and receptor-specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific carnivorous mammals.

**Equation**

$$D_{CM} = (C_{HB} \cdot IR_{CM} \cdot P_{HB} \cdot F_{HB}) + (C_{OB} \cdot IR_{CM} \cdot P_{OB} \cdot F_{OB}) + (C_{OM} \cdot IR_{CM} \cdot P_{OM} \cdot F_{OM}) + (C_{HM} \cdot IR_{CM} \cdot P_{HM} \cdot F_{HM}) \\ + (C_s \cdot IR_{S-CM} \cdot P_s) + (C_{wctot} \cdot IR_{W-CM} \cdot P_w)$$

| Variable | Description                                | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

(Page 7 of 8)

| Variable    | Description                                       | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|---------------------------------------------------|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$ | Total COPC concentration in water column          | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values. Uncertainties may also be associated with the variable <math>L_T</math> and <math>K_w</math>.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $IR_{W-CM}$ | Water ingestion rate for carnivorous mammal       | L/kg BW-day                                            | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in, Table 5-1. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Water ingestion rates are strongly influenced by animal behavior and environmental factors and may over- or under- estimate <math>BCF_{W-CM}</math> to an unknown degree.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| $P_w$       | Proportion of ingested water that is contaminated | unitless                                               | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. TABLE F-2-6

**COPC DOSE INGESTED TERMS IN CARNIVOROUS BIRDS  
IN FOREST, SHORTGRASS PRAIRIE, TALLGRASS PRAIRIE, AND SHRUB/SCRUB FOOD WEBS**

(Page 1 of 8)

**Description**

This equation calculates the potential daily dose through exposure to contaminated food/prey, soil, and water in carnivorous birds in upland forest, shortgrass prairie, tallgrass prairie, and shrub/scrub food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_s$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables will be site-specific.
- (2) Variables  $BCF_{S-CB}$  and  $BCF_{W-CB}$  are based on biotransfer factors for chicken ( $Ba_{chicken}$ ), and receptor-specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific carnivorous birds.

**Equation**

$$D_{CB} = (C_{HB} \cdot IR_{CB} \cdot P_{HB} \cdot F_{HB}) + (C_{OM} \cdot IR_{CB} \cdot P_{OM} \cdot F_{OM}) + (C_{HM} \cdot IR_{CB} \cdot P_{HM} \cdot F_{HM}) \\ + (C_{OB} \cdot IR_{CB} \cdot P_{OB} \cdot F_{OB}) + (C_s \cdot IR_{S-CB} \cdot P_s) + (C_{wctot} \cdot IR_{W-CB} \cdot P_w)$$

|-----------|--------------------------------------------------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $IR_{CB}$ | Food ingestion rate of carnivorous bird                      | kg WW/kg DW-day | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Table 5-1. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</li> <li>(2) IR values may over- or under- estimate exposure when applied for site-specific receptors.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| $P_{HB}$  | Proportion of herbivorous birds in diet that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| $F_{HB}$  | Fraction of diet comprised of herbivorous birds              | unitless        | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of herbivorous birds. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

| Variable | Description                                               | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------|-----------------------------------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{OM}$ | Concentration of COPC in omnivorous mammals               | mg COPC/kg FW tissue | <p style="text-align: center;"><b>Varies (calculated - Table F-1-5)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-5. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Variables <math>C_s</math> and <math>C_{wctot}</math> are COPC- and site-specific. Uncertainties associated with these variables will be site-specific.</li> <li>(2) Variables <math>BCF_{S-OM}</math> and <math>BCF_{W-OM}</math> are based on biotransfer factors for beef (<math>Ba_{beef}</math>), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations for site-specific omnivorous mammals.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $P_{OM}$ | Proportion of omnivorous mammal diet that is contaminated | unitless             | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| $F_{OM}$ | Fraction of diet comprised of omnivorous mammals          | unitless             | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of omnivorous mammals. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| $F_{OB}$ | Fraction of diet comprised of omnivorous birds          | unitless             | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of omnivorous birds. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

TABLE F-2-7

**COPC DOSE INGESTED TERMS IN HERBIVOROUS MAMMALS  
IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 1 of 6)

**Description**

This equation calculates the daily dose through the ingestion of contaminated food/prey, sediment, and water in aquatic herbivorous mammals in freshwater marsh, brackish/intermediate marsh, and saltwater marsh food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_{sed}$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables will be site-specific.
- (2) Variables  $BCF_{BS-HM}$ , and  $BCF_{W-HM}$  are based on biotransfer factors for beef cattle ( $Ba_{beef}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific herbivorous mammals.

**Equation**

$$D_{HM} = (C_{AV} \cdot IR_{HM} \cdot P_{AV} \cdot F_{AV}) + (C_{AL} \cdot IR_{HM} \cdot P_{AL} \cdot F_{AL}) + (C_{sed} \cdot IR_{S-HM} \cdot P_S) + (C_{wctot} \cdot IR_{W-HM} \cdot P_W)$$

| Variable  | Description                                                   | Units           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|---------------------------------------------------------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $IR_{HM}$ | Food ingestion rate of aquatic herbivorous mammal             | kg WW/kg BW-day | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Chapter 5, Table 5-1. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</li> <li>(2) <math>IR</math> values may over- or under- estimate exposure when applied for site-specific receptors.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| $P_{AV}$  | Proportion of aquatic vegetation in diet that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| $F_{AV}$  | Fraction of diet comprised of aquatic vegetation              | unitless        | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic vegetation. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

| Variable    | Description                                              | Units                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{sed}$   | COPC concentration in bed sediment                       | mg COPC/kg DW sediment | <p style="text-align: center;"><b>Varies (calculated - Table B-2-19)</b></p> <p>This equation calculates the concentration of COPCs in bed sediments. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The default variable values recommended for use in the equation in Table B-2-19 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with default variable values is expected to be limited either because the probable ranges for these variables are narrow or because information allowing reasonable estimates is generally available.</li> <li>(2) Uncertainties associated with variables <math>f_{bs}</math>, <math>C_{wctot}</math> and <math>Kd_{bs}</math> are largely associated with the use of default OC content values in their calculation. The uncertainty may be significant in specific instances, because OC content is known to vary widely in different locations in the same medium. This variable is site-specific.</li> </ol> |
| $IR_{S-HM}$ | Sediment ingestion rate for aquatic herbivorous mammal   | kg DW/kg BW-day        | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is site-, receptor-, and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) <math>IR_s</math> values may under- or over-estimate <math>BCF_s</math> when applied for site-specific organisms.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| $P_s$       | Proportion of ingested bed sediment that is contaminated | unitless               | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of sediment ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for a screening level risk assessment when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated soil ingested by species depends on site-specific information, receptor homerange, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of soil ingested that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                       |

IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALT MARSH FOOD WEBS**

(Page 5 of 6)

| Variable    | Description                                         | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|-----------------------------------------------------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$ | Total COPC concentration in water column            | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values. Uncertainties may also be associated with the variable <math>L_T</math> and <math>k_{wt}</math>.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $IR_{W-HM}$ | Water ingestion rate for aquatic herbivorous mammal | L/kg-BW-day                                            | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Water ingestion rates are influenced by animal behavior and environmental factors and may over- or under-estimate <math>BCF_{W-HM}</math> to an unknown degree.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| $P_w$       | Proportion of ingested water that is contaminated   | unitless                                               | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. | <p>This equation calculates the daily dose through ingestion of contaminated food/prey, sediment, and water in aquatic herbivorous birds in freshwater marsh, brackish/intermediate marsh, and saltwater marsh food webs. The limitations and uncertainties introduced in calculating this variable include the following:</p> <p>(1) Variables <math>C_{sed}</math> and <math>C_{wctot}</math> are COPC- and site-specific. Uncertainties associated with these variables will be site-specific.</p> <p>(2) Variables <math>BCF_{S-HB}</math> and <math>BCF_{W-HB}</math> are based on biotransfer factors for chicken (<math>Ba_{chicken}</math>), and receptor-specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific herbivorous birds.</p> |                                                 |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| $D_{HB}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Dose ingested for herbivorous birds             | mg/kg BW-day    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $C_{AV}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Concentration of COPC in aquatic vegetation     | mg COPC/kg WW   | <p><b>Varies (calculated - Table F-1-7)</b></p> <p>This variable is site- and COPC-specific; it is calculated using the equation in Table F-1-7. Uncertainties associated with this variable include:</p> <p>(1) <math>C_{sed}</math> values are COPC- and site-specific.</p> <p>(2) <math>BCF_{S-AV}</math> values are intended to represent “generic aquatic vegetation species”, and therefore may over- or under-estimate exposure when applied to site-specific vegetation.</p>                                                                                                                                                                                                                                                    |
| $IR_{HB}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Food ingestion rate of aquatic herbivorous bird | kg WW/kg BW-day | <p><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Chapter 5, Table 5-1. Uncertainties associated with this variable include:</p> <p>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</p> <p>(2) IR values may over- or under- estimate exposure when applied for site-specific receptors.</p> |

| Variable | Description                                                   | Units         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|---------------------------------------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_{AV}$ | Proportion of aquatic vegetation in diet that is contaminated | unitless      | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $F_{AV}$ | Fraction of diet comprised of aquatic vegetation              | unitless      | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic vegetation. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |
| $C_{AL}$ | Concentration of COPC in algae                                | mg COPC/kg WW | <p style="text-align: center;"><b>Varies (calculated - Table F-1-8)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-8. Uncertainties associated with this variable include:</p> <p>(1) <math>C_{dw}</math> values are COPC- and site-specific. Uncertainties associated with this variable will be site-specific.</p> <p>(2) <math>BCF_{W-AL}</math> values are intended to represent “generic algae species”, and therefore may over- or under-estimate exposure when applied to site-specific species.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

IN FRESHWATER/WETLAND, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 5 of 6)

| Variable    | Description                                       | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|---------------------------------------------------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$ | Total COPC concentration in water column          | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values. Uncertainties may also be associated with the variable <math>L_T</math> and <math>k_{wt}</math>.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $IR_{W-HB}$ | Water ingestion rate for aquatic herbivorous bird | L/kg BW-day                                            | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5, Section 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Water ingestion rates are influenced by animal behavior and environmental factors and may over- or under-estimate <math>BCF_{W-HB}</math> to an unknown degree.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $P_w$       | Proportion of ingested water that is contaminated | unitless                                               | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. IN FRESHWATER/WETLAND MARSH, BRACKISH/INTERMEDIATE MARSH, AND SALTMARSH FOOD WEBS**

(Page 1 of 10)

**Description**

This equation calculates the daily dose through ingestion of contaminated food/prey, sediment, and water in aquatic omnivorous mammals in freshwater marsh, brackish/intermediate marsh, and saltwater marsh food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_{sed}$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables will be site-specific.
- (2) Variables  $BCF_{S-OM}$  and  $BCF_{W-OM}$  are based on biotransfer factors for beef cattle ( $Ba_{beef}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific omnivorous mammals.

**Equation**

$$D_{OM} = (C_{HM} \cdot IR_{OM} \cdot P_{HM} \cdot F_{HM}) + (C_{HB} \cdot IR_{OM} \cdot P_{HB} \cdot F_{HB}) + (C_{BI} \cdot IR_{OM} \cdot P_{BI} \cdot F_{BI}) + (C_{WI} \cdot IR_{OM} \cdot P_{WI} \cdot F_{WI}) \\ + (C_{AV} \cdot IR_{OM} \cdot P_{AV} \cdot F_{AV}) + (C_{AL} \cdot IR_{OM} \cdot P_{AL} \cdot F_{AL}) + (C_{sed} \cdot IR_{S-OM} \cdot P_S) + (C_{wctot} \cdot IR_{W-OM} \cdot P_W)$$

| $IR_{OM}$ | Food ingestion rate of aquatic omnivorous mammal                      | kg WW/kg BW-day | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Chapter 5, Table 5-1. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</li> <li>(2) IR values may over- or under- estimate exposure when applied for site-specific receptors.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $P_{HM}$  | Proportion of aquatic herbivorous mammal in diet that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| $F_{HM}$  | Fraction of diet comprised of aquatic herbivorous mammals             | unitless        | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic herbivorous mammals. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

IN BRACKISH/INTERMEDIATE MARSH, SALTMARSH, AND FRESHWATER/WETLAND FOOD WEBS**

(Page 1 of 7)

**Description**

This equation calculates the daily dose through ingestion of contaminated food/prey, sediment, and water in aquatic omnivorous birds in freshwater marsh, brackish/intermediate marsh, and saltwater marsh food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_{sed}$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables will be site-specific.
- (2) Variables  $BCF_{S-OB}$  and  $BCF_{W-OB}$  are based on biotransfer factors for chicken ( $Ba_{chicken}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific omnivorous birds.

**Equation**

$$D_{OB} = (C_{BI} \cdot IR_{OB} \cdot P_{BI} \cdot F_{BI}) + (C_{WI} \cdot IR_{OB} \cdot P_{WI} \cdot F_{WI}) + (C_{AV} \cdot IR_{OB} \cdot P_{AV} \cdot F_{AV}) \\ + (C_{AL} \cdot IR_{OB} \cdot P_{AL} \cdot F_{AL}) + (C_{sed} \cdot IR_{S-OB} \cdot P_S) + (C_{wctot} \cdot IR_{W-OB} \cdot P_W)$$

| Variable | Description                                    | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|------------------------------------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $D_{OB}$ | Dose ingested for aquatic omnivorous birds     | mg/kg BW-day         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| $C_{BI}$ | Concentration of COPC in benthic invertebrates | mg COPC/kg FW tissue | <p><b>Varies (calculated - Table F-1-11)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-11. Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) <math>C_{sed}</math> values are COPC- and site-specific.</li> <li>(2) <math>BCF_{S-BI}</math> values are intended to represent “generic benthic invertebrate species”, and therefore may over- or under-estimate exposure when applied to site-specific organisms.</li> </ol> |

| $IR_{OB}$ | Food ingestion rate of aquatic omnivorous bird                  | kg WW/kg BW-day | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Chapter 5, Table 5-1. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</li> <li>(2) IR values may over- or under- estimate exposure when applied for site-specific receptors.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| $P_{BI}$  | Proportion of benthic invertebrate in diet that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| $F_{BI}$  | Fraction of diet comprised of benthic invertebrates             | unitless        | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of benthic invertebrates. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

| $C_{AV}$ | Concentration of COPC in aquatic vegetation ingested by the animal | mg COPC/kg WW | <p style="text-align: center;"><b>Varies (calculated - Table F-1-7)</b></p> <p>This variable is site- and COPC-specific; it is calculated using the equation in Table F-1-7. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) <math>C_{sed}</math> values are COPC- and site-specific.</li> <li>(2) <math>BCF_{S-AV}</math> values are intended to represent “generic aquatic vegetation species”, and therefore may over- or under-estimate exposure when applied to site-specific vegetation.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| $P_{AV}$ | Proportion of aquatic vegetation in diet that is contaminated      | unitless      | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| $F_{AV}$ | Fraction of diet comprised of aquatic vegetation                   | unitless      | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic vegetation. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

IN BRACKISH/INTERMEDIATE MARSH, SALTMARSH, AND FRESHWATER/WETLAND FOOD WEBS**

(Page 6 of 7)

| Variable    | Description                                      | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|--------------------------------------------------|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$ | Total COPC concentration in water column         | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values. Uncertainties may also be associated with the variable <math>L_T</math> and <math>k_{wt}</math>.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same media, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $I.W.-OB$   | Water ingestion rate for aquatic omnivorous bird | L/kg BW-day                                            | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. **EQUATIONS FOR COMPUTING COPC DOSE INGESTED TERMS IN CARNIVOROUS MAMMALS  
IN BRACKISH/INTERMEDIATE MARSH, SALTMARSH, AND FRESHWATER/WETLAND FOOD WEBS**

(Page 1 of 10)

**Description**

This equation calculates the daily dose through exposure to food/prey, sediment, and water in aquatic carnivorous mammals in freshwater marsh, brackish/intermediate marsh, and saltwater marsh food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_{sed}$  and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables will be site-specific
- (2) Variables  $BCF_{S-CM}$  and  $BCF_{W-CM}$  are based on biotransfer factors for beef cattle ( $Ba_{beef}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific carnivorous mammals.

**Equation**

$$D_{CM} = (C_{HB} \cdot IR_{CM} \cdot P_{HB} \cdot F_{HB}) + (C_{OF} \cdot IR_{CM} \cdot P_{OF} \cdot F_{OF}) + (C_{CF} \cdot IR_{CM} \cdot P_{CF} \cdot F_{CF}) + (C_{OB} \cdot IR_{CM} \cdot P_{OB} \cdot F_{OB}) \\ + (C_{OM} \cdot IR_{CM} \cdot P_{OM} \cdot F_{OM}) + (C_{HM} \cdot IR_{CM} \cdot P_{HM} \cdot F_{HM}) + (C_{sed} \cdot IR_{S-CM} \cdot P_S) + (C_{wctot} \cdot IR_{W-CM} \cdot P_W)$$

| Variable  | Description                                                  | Units           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $IR_{CM}$ | Food ingestion rate of carnivorous mammal                    | kg WW/kg BW-day | <p align="center"><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Chapter 5, Table 5-1. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</li> <li>(2) IR values may over- or under- estimate exposure when applied for site-specific receptors.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| $P_{HB}$  | Proportion of herbivorous birds in diet that is contaminated | unitless        | <p align="center"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| $F_{HB}$  | Fraction of diet comprised of herbivorous birds              | unitless        | <p align="center"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic herbivorous birds. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

| $C_{HM}$ | Concentration of COPC in herbivorous mammals                  | mg COPC/kg FW tissue | <p align="center"><b>Varies (calculated - Table F-1-9)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-9. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>Variables <math>C_{sed}</math> and <math>C_{wctot}</math> are COPC- and site-specific.</li> <li>Variables <math>BCF_{S-HM}</math> and <math>BCF_{W-HM}</math> are based on biotransfer factors for beef cattle (<math>Ba_{beef}</math>), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute concentrations for site-specific aquatic herbivorous mammals.</li> </ol>                                                                                                                                                                                                                                                           |
| $P_{HM}$ | Proportion of herbivorous mammal in diet that is contaminated | unitless             | <p align="center"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                 |
| $F_{HM}$ | Fraction of diet comprised of herbivorous mammals             | unitless             | <p align="center"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of aquatic herbivorous mammals. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>The actual proportion of the diet that is comprised of herbivorous mammals depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. Therefore a default value of 100 percent for the exclusive diet, may over-estimate dietary exposure.</li> </ol> |

**COPC DOSE INGESTED TERMS IN CARNIVOROUS BIRDS  
IN BRACKISH/INTERMEDIATE MARSH, SALTMARSH, AND FRESHWATER/WETLAND FOOD WEBS**

(Page 1 of 11)

**Description**

This equation calculates the daily dose through exposure to contaminated food/prey, soil, and water in aquatic carnivorous birds in freshwater marsh, brackish/intermediate marsh, and saltwater marsh food webs. The limitations and uncertainties introduced in calculating this variable include the following:

- (1) Variables  $C_{sed}$ , and  $C_{wctot}$  are COPC- and site-specific. Uncertainties associated with these variables will be site-specific.
- (2) Variables  $BCF_{BS-CB}$ , and  $BCF_{W-CB}$  are based on biotransfer factors for chicken ( $Ba_{chicken}$ ), and receptor specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific carnivorous birds.

**Equation**

$$D_{CB} = (C_{OF} \cdot IR_{CB} \cdot P_{OF} \cdot F_{OF}) + (C_{CF} \cdot IR_{CB} \cdot P_{CF} \cdot F_{CF}) + (C_{OM} \cdot IR_{CB} \cdot P_{OM} \cdot F_{OM}) + (C_{HM} \cdot IR_{CB} \cdot P_{HM} \cdot F_{HM}) \\ + (C_{OB} \cdot IR_{CB} \cdot P_{OB} \cdot F_{OB}) + (C_{HB} \cdot IR_{CB} \cdot P_{HB} \cdot F_{HB}) + (C_{sed} \cdot IR_{S-CB} \cdot P_S) + (C_{wctot} \cdot IR_{W-CB} \cdot P_W)$$

| Variable  | Description                                             | Units           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $IR_{CB}$ | Food ingestion rate of carnivorous birds                | kg WW/kg BW-day | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Chapter 5, Table 5-1. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</li> <li>(2) <math>IR</math> values may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| $P_{OF}$  | Proportion of omnivorous fish diet that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| $F_{OF}$  | Fraction of diet comprised of omnivorous fish           | unitless        | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of omnivorous fish. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |

(Page 8 of 11)

| Variable    | Description                                           | Units                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|-------------------------------------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{sed}$   | COPC concentration in bed sediment                    | mg COPC/kg DW sediment | <p><b>Varies (calculated - Table B-2-19)</b></p> <p>This equation calculates the concentration of COPCs in bed sediments. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The default variable values recommended for use in the equation in Table B-2-19 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with default variable values is expected to be limited either because the probable ranges for these variables are narrow or because information allowing reasonable estimates is generally available.</li> <li>(2) Uncertainties associated with variables <math>f_{bs}</math>, <math>C_{wctot}</math> and <math>Kd_{bs}</math> are largely associated with the use of default OC content values in their calculation. The uncertainty may be significant in specific instances, because OC content is known to vary widely in different locations in the same medium. This variable is site-specific.</li> </ol> |
| $IR_{S-CB}$ | Sediment ingestion rate for carnivorous bird          | kg DW/kg BW-day        | <p><b>Varies</b></p> <p>This variable is site-, receptor-, and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) <math>IR_s</math> values may under- or over-estimate <math>BCF_s</math> when applied to site-specific organisms.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| $P_s$       | Portion of ingested bed sediment that is contaminated | unitless               | <p><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of soil ingested that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for a screening level risk assessment when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated soil ingested by species depends on site-specific information, receptor homerange, and animal behavior; therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and the proportion of soil ingested that is contaminated will likely be overestimated.</li> </ol>                                                                                                                                                                                                                                                                           |

IN BRACKISH/INTERMEDIATE MARSH, SALTMARSH, AND FRESHWATER/WETLAND FOOD WEBS**

(Page 9 of 11)

| Variable    | Description                                       | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|---------------------------------------------------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$ | Total COPC concentration in water column          | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values. Uncertainties may also be associated with the variable <math>L_T</math> and <math>k_{wt}</math>.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $IR_{W-CB}$ | Water ingestion rate for aquatic carnivorous bird | L/kg BW-day                                            | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Water ingestion rates are strongly influenced by animal behavior and environmental factors and may over- or under- estimate <math>BCF_{W-HM}</math> to an unknown degree.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <p>This equation calculates the daily dose through exposure to contaminated food/prey, sediment, and water in carnivorous shore birds in freshwater marsh, brackish/intermediate marsh, and saltwater marsh food webs. The limitations and uncertainties introduced in calculating this variable include the following:</p> <p>(1) Variables <math>C_{sed}</math> and <math>C_{wctot}</math> are COPC- and site-specific. Uncertainties associated with these variables will be site-specific</p> <p>(2) Variables <math>BCF_{S-CSB}</math>, and <math>BCF_{W-CSB}</math> are based on biotransfer factors for chicken (<math>Ba_{chicken}</math>), and receptor-specific ingestion rates, and therefore may introduce uncertainty when used to compute a representative daily dose for site-specific carnivorous birds.</p> |                                                |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| $C_{BI}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Concentration of COPC in benthic invertebrates | mg COPC/kg FW tissue | <p><b>Varies (calculated - Table F-1-11)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-11. Uncertainties associated with this variable include the following:</p> <p>(1) <math>C_{sed}</math> values are COPC- and site-specific.</p> <p>(2) <math>BCF_{S-BI}</math> values are intended to represent “generic benthic invertebrate species”, and therefore may over- or under-estimate exposure when applied to site-specific organisms.</p> |

TABLE F-2-13

**COPC DOSE INGESTED TERMS IN CARNIVOROUS SHORE BIRDS  
IN BRACKISH/INTERMEDIATE MARSH, SALTMARSH, AND FRESHWATER/WETLAND FOOD WEBS**

(Page 2 of 10)

| Variable   | Description                                                     | Units           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|-----------------------------------------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $IR_{CSB}$ | Food ingestion rate of carnivorous shore birds                  | kg WW/kg BW-day | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are provided in Chapter 5, Table 5-1. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) Food ingestion rates are influenced by several factors including: metabolic rate, energy requirements for growth and reproduction, and dietary composition. Ingestion rates are also influenced by ambient temperature, receptor activity level and body weight U.S. EPA (1993). These factors introduce an unknown degree of uncertainty when used to estimate daily dose.</li> <li>(2) <math>IR</math> values may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |
| $P_{BI}$   | Proportion of benthic invertebrate in diet that is contaminated | unitless        | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                              |

TABLE F-2-13

**COPC DOSE INGESTED TERMS IN CARNIVOROUS SHORE BIRDS  
IN BRACKISH/INTERMEDIATE MARSH, SALTMARSH, AND FRESHWATER/WETLAND FOOD WEBS**

(Page 3 of 10)

| Variable | Description                                                   | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|---------------------------------------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $F_{BI}$ | Fraction of diet comprised of benthic invertebrates           | unitless             | <p><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of benthic invertebrates. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</li> <li>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</li> <li>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</li> </ol> |
| $C_{WI}$ | Concentration of COPC in water invertebrates                  | mg COPC/kg FW tissue | <p><b>Varies (calculated - Table F-1-12)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in Table F-1-12. Uncertainties associated with this variable include:</p> <ol style="list-style-type: none"> <li>(1) <math>C_{dw}</math> values are COPC- and site-specific.</li> <li>(2) <math>BCF_{W-WI}</math> values are intended to represent “generic water invertebrate species”, and therefore may over- or under- estimate exposure when applied to site-specific organisms.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $P_{WI}$ | Proportion of water invertebrate in diet that is contaminated | unitless             | <p><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|----------|------------------------------------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $P_{OB}$ | Proportion of omnivorous bird in diet that is contaminated | unitless             | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| $F_{OB}$ | Fraction of diet comprised of omnivorous birds             | unitless             | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of omnivorous birds. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |
| $C_{OF}$ | Concentration of COPC in omnivorous fish                   | mg COPC/kg FW tissue | <p style="text-align: center;"><b>Varies (calculated - Table F-1-16)</b></p> <p>This variable is site-specific and COPC-specific; it is calculated using the equation in F-1-16. Uncertainties associated with this variable include:</p> <p>(1) <math>C_{dw}</math> values are COPC- and site-specific.</p> <p>(2) The data set used to calculate <math>BCF_{fish}</math> is based on a limited number of test organisms and therefore may over- or under-estimate exposure when applied to site-specific organisms.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| $P_{OF}$ | Proportion of omnivorous fish diet that is contaminated | unitless | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the dietary food item that is contaminated. U.S. EPA OSW recommends that a default value of 1.0 be used for all food types when site specific information is not available. The following uncertainty is associated with this variable:</p> <p>(1) The actual amount of contaminated food ingested by a species depends on food availability, diet composition, and animal behavior. Therefore, the default value of 100 percent may not accurately reflect site-specific conditions, and may overestimate the proportion of contaminated food ingested.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| $F_{OF}$ | Fraction of diet comprised of omnivorous fish           | unitless | <p style="text-align: center;"><b>0 to 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of the diet that is comprised of omnivorous fish. The default value for a screening level ecological risk assessment is 100 percent for computing concentration based on an exclusive diet. For calculating an equal diet, <math>F_{diet}</math> is determined based on the number of dietary components in the total diet. The application of an equal diet is further discussed in Chapter 5.</p> <p>Uncertainties associated with this variable include:</p> <p>(1) The actual proportion of the diet that is comprised of a specific dietary item depends on several factors including: food availability, animal behavior, species composition, and seasonal influences. These uncertainties may over- or under- estimate <math>F_{diet}</math> when applied to site-specific receptors.</p> <p>(2) The default value of 100 percent for an exclusive diet introduces uncertainty and may over-estimate exposure from ingestion of a single dietary item.</p> <p>(3) The default value for an equal diet introduces uncertainty and may over- or under- estimate exposure when applied to site-specific receptors.</p> |

| Variable     | Description                                    | Units                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|------------------------------------------------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $C_{wctot}$  | Total COPC concentration in water column       | mg COPC/L water<br>(or<br>g COPC/m <sup>3</sup> water) | <p style="text-align: center;"><b>Varies (calculated - Table B-2-17)</b></p> <p>This variable is COPC- and site-specific and is calculated using Table B-2-17. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in the equation in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>C_{wctot}</math>.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default OC content values. Uncertainties may also be associated with the variable <math>L_T</math> and <math>k_{wt}</math>.</li> </ol> <p>The degree of uncertainty associated with the variables <math>d_{wc}</math> and <math>d_{bs}</math> is expected to be minimal either because information for estimating a variable (<math>d_{wc}</math>) is generally available or because the probable range for a variable (<math>d_{bs}</math>) is narrow. The uncertainty associated with the variables <math>f_{wc}</math> and <math>C_{wctot}</math> is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.</p> |
| $IR_{W-CSB}$ | Water ingestion rate for carnivorous shorebird | L/kg BW-day                                            | <p style="text-align: center;"><b>Varies</b></p> <p>This variable is receptor- and habitat-specific, and is discussed in Chapter 5. Ingestion rates for example measurement receptors are presented in Chapter 5, Table 5-1. The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Water ingestion rates are strongly influenced by animal behavior and environmental factors and may over- or under- estimate <math>BCF_{W-CSB}</math> to an unknown degree.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $P_w$        | Portion of ingested water that is contaminated | unitless                                               | <p style="text-align: center;"><b>0 to 1</b><br/><b>Default: 1</b></p> <p>This variable is species- and site-specific, and depends on the percentage of water ingested that is contaminated. ## **ACETONE**

### **1.0 SUMMARY**

Acetone is a highly volatile organic compound. Volatilization and biodegradation are the major fate processes affecting acetone released to soil, surface water, and sediment. Routes of exposure for wildlife include ingestion, inhalation, and dermal uptake. Acetone is not bioconcentrated by aquatic organisms, and is not bioaccumulated by mammals and birds. Therefore, it does not bioaccumulate in aquatic or terrestrial food chains.

The following is a profile of the fate of acetone in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER AND SEDIMENT**

Volatilization and leaching are the two primary transport properties affecting the fate of acetone in soils (HSDB 1997). Volatilization is more significant than leaching. The extent of leaching depends on soil characteristics. Evidence also suggests that acetone rapidly degrades in soil (HSDB 1997).

Volatilization and biodegradation are the major fate processes affecting the fate of acetone in surface water. The volatilization half-life for acetone from a model river is approximately 18 hours when estimated using 1-meter depth, a current of 1 m/second, and wind velocity of 3 m/second (Thomas 1982). In addition, acetone does not partition well to sediments because it is highly soluble in water. Dispersion of acetone from the water column to sediment and suspended solids in water is likely to be insignificant, due to the complete miscibility of acetone in water.

Biodegradation is the most significant degradation process of acetone in water (Rathbun et al. 1982). Studies on wastewater have shown that aquatic microbial communities quickly acclimate to acetone, and rapidly biodegrade it (Urano and Kato 1986a,b). When tested in seawater, acetone was biodegraded much slower than when tested in freshwater (Takemoto et al. 1981).

Photolysis as a degradation process for acetone in water is insignificant. Studies have shown that photodecomposition was not observed when acetone contaminated distilled or natural water was exposed to sunlight for 2-3 days (Rathbun et al. 1982).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

For most aquatic systems, acetone will exist in water rather than sediment, due to acetone's high water solubility and low sediment adsorption coefficient. Bioaccumulation does not occur in aquatic organisms as suggested by the low log  $K_{ow}$  value for acetone (Rathbun et al. 1982). Adult haddock tested under static conditions at 7.9°C showed a bioconcentration factor of 1 for acetone (Rustung et al. 1931). Biomagnification along the aquatic food chain is also considered insignificant for acetone as suggested by the low  $K_{ow}$  value.

Acetone is a highly volatile compound and may be inhaled in large quantities. Acetone is very water soluble, so it is quickly absorbed following inhalation into the blood stream and dispersed throughout the body. A large portion of acetone is excreted primarily unchanged through the lungs and urine, with only a small portion reduced and excreted as carbon dioxide (Encyclopedia of Occupational Health and Safety 1983). Because acetone is quickly eliminated, wildlife receptors will not accumulate it in tissues.

No information was available on the fate of acetone after exposure by birds or plants.

## **ACRYLONITRILE**

### **1.0 SUMMARY**

Acrylonitrile is a highly water soluble volatile organic compound. Volatilization and biodegradation are the major fate processes affecting acrylonitrile released to surface soil, surface water, and sediment. Routes of exposure for wildlife include ingestion, inhalation, and dermal uptake. Acrylonitrile is not bioconcentrated by aquatic organisms, and is not bioaccumulated by mammals and birds. Therefore, it does not bioaccumulate in aquatic or terrestrial food chains.

The following is a profile of the fate of acrylonitrile in soil, surface water, and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in surface soil, surface water, and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

Due to its high water solubility, acrylonitrile is highly mobile in moist soils (EPA 1987). Adsorption into the soil is considered insignificant (Kenaga 1980). Evaporation of acrylonitrile from dry soils is expected to occur rapidly because of its high vapor pressure (Norris 1967; EPA 1987) and high Henry's Law constant (Meylan 1991).

Acrylonitrile is readily soluble in water and does not strongly adsorb to soil or sediment (Klein et al. 1957; ATSDR 1990). Acrylonitrile biodegrades rapidly in water (Miller and Villaume 1978; EPA 1987). Aerobic microorganisms readily degrade acrylonitrile, particularly if acclimation time is allowed (Cherry et al. 1956; Stover and Kincannon 1983; Mills and Stack 1954, 1955).

Acrylonitrile rapidly volatilizes from surface water. A volatilization half-life of 1-6 days in water has been estimated (Thomas 1982; HSDB 1997).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Based on experimental and estimated bioconcentration factors, the bioconcentration of acrylonitrile in aquatic organisms is not believed to be significant (Kenaga 1980). A steady-state bioconcentration factor

(BCF) of 48 was measured in bluegill sunfish (Barrows et al. 1978). The estimated average BCF for edible portions of freshwater and marine species was approximately 30 based on the relative proportion of fat in sunfish and other organisms (EPA 1980). Also, based on a low log  $K_{ow}$ , acrylonitrile is estimated to show low bioconcentration in aquatic organisms (Verschuere 1983; Kenaga 1980).

Acrylonitrile is readily absorbed into the body through lung and intestinal mucosa following inhalation, ingestion, or dermal contact (Clayton and Clayton 1982). Once absorbed into the body, acrylonitrile is distributed throughout the body to the major organs (Pilon et al. 1988a). Following a single oral dose of radiolabeled acrylonitrile, rapid distribution of acrylonitrile and its metabolites was shown in all tissues of rats (Ahmed et al. 1982, 1983; Silver et al. 1987; Young et al. 1968). Another metabolic pathway includes the formation of  $CO_2$  which is excreted via the lungs (Young et al. 1968). The rate of acrylonitrile metabolism is inconclusive; however, evidence suggests that it is rapid (Pilon et al. 1988b; Ghanayem and Ahmed 1982; Miller and Villaume 1978). Values representing the amount of acrylonitrile metabolized range from 4% to 30% (IARC 1979).

No information was available on the fate of acrylonitrile after exposure by birds or plants.

## **ALUMINUM**

### **1.0 SUMMARY**

In nature, aluminum does not exist in the elemental state, but partitions between the liquid and solid phases by forming complexes with various compounds. Aluminum adsorbs to clays and suspended solids in water. Exposure routes for aquatic organisms include ingestion, gill uptake and dermal contact. Aluminum bioconcentrates in aquatic organisms. Exposure routes for mammals include ingestion, inhalation and dermal exposure; however, regardless of the route of exposure, aluminum is poorly absorbed by mammals. Aluminum is not readily metabolized. Aluminum causes pulmonary and developmental effects. Aluminum uptake by plants varies between species, resulting in differing rates of bioconcentration in plant tissues.

The following is a profile of the fate of aluminum in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER AND SEDIMENT**

Aluminum does not exist as a free metal in nature due to its reactivity, but rather partitions between the solid and liquid phases by reacting with water, chloride, fluoride, sulfate, nitrate, phosphate, humic materials and clay (Bodek et al. 1988). Soils with a greater mineral content result in reduced mobility of aluminum (James and Riha 1989).

In water, aluminum forms relatively water-insoluble complexes, or is found as a water-soluble complex. Aluminum adsorbs to suspended solids and sediment. If large amounts of organic matter or fulvic acid are present, aluminum binds to them (Brusewitz 1984). In water, aluminum undergoes hydrolysis to form hydroxy aluminum species (Snoeyink and Jenkins 1980). The pH of the water determines which hydrolysis products are formed.

### **3.0 ECOLOGICAL RECEPTORS**

Exposure routes for aquatic organisms include ingestion, gill uptake, and dermal absorption. Aluminum bioconcentrates in aquatic species (Cleveland et al. 1989).

Exposure routes for mammals include ingestion, inhalation and dermal exposure. Aluminum is poorly absorbed. Aluminum is distributed to the brain (Santos et al. 1987), bone, muscle and kidneys (Greger and Donnaubauer 1986). No studies were located that described excretion of aluminum in animals; however in humans, absorbed aluminum is excreted primarily through the kidney (Gorsky et al. 1979).

Information was not available on the fate of aluminum in birds.

Aluminum is taken up by plants (Brusewitz 1984). Some plants bioaccumulate aluminum in the root tissues. Plant uptake of aluminum and the transport to stems and leaves varies considerably between species (Kabata-Pendias and Pendias 1984).

## **ANTIMONY**

### **1.0 SUMMARY**

Antimony binds to soil and particulates and is oxidized by bacteria in soil. Exposure routes for aquatic organisms include ingestion and gill uptake. Antimony bioconcentrates in aquatic organisms. Exposure routes for mammals include ingestion and inhalation. It does not biomagnify in terrestrial food chains. Antimony is not significantly metabolized and is excreted in the urine and the feces. Antimony causes reproductive, pulmonary and hepatic effects in mammals. Antimony uptake by plants occurs following surface deposition.

The following is a profile of the fate of antimony in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER AND SEDIMENT**

Antimony binds to soil, particularly to particles containing iron, manganese, or aluminum Ainsworth 1988). In water, antimony is oxidized when exposed to atmospheric oxygen (Parris and Brinckman 1976).

### **3.0 ECOLOGICAL RECEPTORS**

Exposure routes for aquatic organisms include ingestion and gill uptake. Antimony bioconcentrates in aquatic organisms (ACQUIRE 1989; Callahan et al. 1979; EPA 1980).

Exposure routes for mammals include ingestion and inhalation (Groth et al. 1986, EPA 1988). Dermal absorption is low (Myers et al. 1978) and absorption from the respiratory tract is dependent on particle size (Thomas et al. 1973). Following absorption, antimony is distributed to the liver, kidney, bone, lung, spleen and thyroid (Sunagawa 1981; Ainsworth 1988). Antimony is excreted in the urine and the feces (Felicetti et al. 1974). Antimony does not biomagnify in the food chain (Ainsworth 1988). Data regarding the amount of antimony that reaches the site of action and assimilation efficiency were not available.

Information was not available on the fate of antimony in birds.

Antimony is taken up by plants following surface deposition, with uptake from soil dependent on the solubility of the antimony in the soil (Ainsworth 1988).

## **ARSENIC**

### **1.0 SUMMARY**

Arsenic, because of its complex chemistry, exists in the environment in many different inorganic and organic forms, which have different toxicological and physicochemical properties. Inorganic arsenic exists as either the trivalent (3+) form or the pentavalent (5+) form. The inorganic trivalent arsenic forms are more toxic than the pentavalent forms. Elemental arsenic (the metalloid -0+) is essentially nontoxic even at high intakes.

Arsenic in soil is usually tightly bound. The bioconcentration potential in soil invertebrates and aquatic species is low. Biomagnification through the food chain is minimal because once ingested, arsenic is metabolized to methylated compounds that are rapidly excreted. Absorbed arsenic is distributed to all tissues where it interferes with normal enzymatic activity or disrupts the functioning of other cellular macromolecules. Evaluation of the potential for toxicity from exposure to low levels of arsenic is complicated by the current understanding that arsenic is an essential element in some mammalian species, and that arsenic deficiency may result in adverse reproductive and developmental effects.

The following is a profile of the fate of arsenic in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

The dominant form of arsenic in soil and its transport are largely dependent on the physical characteristics of the soil matrix. Insoluble arsenic compounds, such as arsenic trioxide, bind tightly to organic matter in soil or sediment (EPA 1984; ATSDR 1993). Various forms of arsenic in soil are interconverted by chemical reactions and microbial activity. Soil microorganisms convert small amounts of arsenic to volatile arsines. These volatile arsines are released to the air, become adsorbed to particles, and are redeposited (ATSDR 1993) or, under certain conditions, react to form oxides (Ghassemi et al. 1981).

The bioavailability of arsenic in soil is inversely proportional to the organic carbon and clay content of the soil matrix. Arsenic in soil is directly taken up by plants and soil microbes and invertebrates, and indirectly taken up by terrestrial receptors via ingestion.

In surface water, soluble inorganic arsenate ( $\text{As}^{5+}$ ) predominates under normal conditions and is more stable than arsenite (EPA 1980a). Movement and partitioning of arsenic in water depends on the chemical form of arsenic and on interactions with other materials present (Callahan et al. 1979). Soluble forms of arsenic remain dissolved in the water column or adsorb onto sediments or soils, especially those containing clays, iron oxides, aluminum hydroxides, manganese compounds, and organic matter (Callahan et al. 1979; Welch et al. 1988). Sediment bound arsenic is released back into the water by chemical or biological interconversions. This interconversion is influenced by the Eh (the oxidation-reduction potential), pH, temperature, other metals, salinity, and biota (Callahan et al. 1979). Arsenate is transformed by microbes to arsenite and methylated arsenicals (Benson 1989; Braman and Foreback 1973).

### **3.0 ECOLOGICAL RECEPTORS**

Exposure routes for aquatic organisms include gill uptake, ingestion of arsenic suspended on particles in the water column or deposited in sediment, and ingestion of plant matter and lower trophic level aquatic species. Arsenic bioconcentration in aquatic organisms is low (Spehar et al. 1980; EPA 1980b). Fish and shellfish rapidly metabolize arsenic to non-toxic forms (EPA 1984, Garcia-Vargas and Cebrian 1996; ATSDR 1993). Biomagnification does not readily occur in aquatic food chains (Callahan et al. 1979).

Soil invertebrates are directly exposed to arsenic found in soil and soil pore water. Exposure routes for soil invertebrates include ingestion and dermal absorption. Arsenic bioconcentration in soil invertebrates is low (Rhett et al. 1988).

The majority of ecological mammalian exposure occurs through ingestion. The oral absorption efficiency is dependent on the form of arsenic, its solubility, and the media ingested. Soluble arsenic compounds in aqueous solution are more readily absorbed from the gastrointestinal tract than insoluble compounds. Absorption from water ingested is approximately 85%. Inorganic arsenic in food sources is expected to be readily bioavailable with absorption rates of greater than 85% expected. Once absorbed, arsenic is readily transported throughout the body with little tendency to accumulate preferentially in any one internal organ

(ATSDR 1993). Dermal absorption is a minor route of exposure with absorption estimated at 0.1% (ATSDR 1993).

Metabolism of arsenic occurs primarily in the liver. The methylated metabolites are less toxic than the inorganic precursors, and metabolism results in lower tissue retention of inorganic arsenic (Marafante and Vahter 1984, 1986, 1987; Marafante et al. 1985). Inorganic arsenic and its methylated products are rapidly eliminated.

The toxicokinetic data for arsenic indicate there is little potential for bioaccumulation in animal tissue exposed to doses that are below the level required to saturate detoxifying methylation reactions. The level of biomagnification in mammals depends on the diet of the animal. Herbivores have a low arsenic biomagnification rate due to the general lack of transport of arsenic from soil to above ground plant parts. Omnivores have a higher biomagnification rate based on the higher proportion of soil invertebrates in their diet. Carnivores have the highest biomagnification rate due to their diet of aquatic invertebrates, small mammals, and fish and the incidental ingestion of soil. However, arsenic is rapidly metabolized in mammalian species, therefore, arsenic does not readily bioaccumulate in mammals.

Exposure routes for avian receptors include ingestion of surface water, soil, soil and aquatic invertebrates, and plant material. Absorption studies specific to avian species are not available. Based on mammalian absorption (ATSDR 1993), avian absorption can be assumed to be 85% absorption from water, 30% to 40% absorption from soil, and 85% absorption from food sources.

Arsenic uptake by plants depends on the form of arsenic and the type of soil. The higher the soil's organic carbon and clay content the more the arsenic will bind to the soil and, therefore, less arsenic is available for uptake by plant roots. That which is readily taken up by the plant is accumulated in the roots. Arsenite (3+) is highly toxic to cell membranes and, therefore, not readily translocated once taken up; arsenate (5+) is less toxic and, therefore, more readily translocated after uptake (ORNL 1996; Speer 1973). Rice, most legumes, and members of the bean family are sensitive to arsenic in most forms, with spinach being the most sensitive plant (Woolson et al 1975).

## **BERYLLIUM**

### **1.0 SUMMARY**

In environmental media, beryllium usually exists as beryllium oxide. Beryllium has limited solubility and mobility in sediment and soil. Exposure routes for aquatic organisms include ingestion and gill uptake. Beryllium does not bioconcentrate in aquatic organisms. Beryllium is toxic to warm water fish, especially in soft water. Exposure routes for mammalian species include inhalation. Mammals exposed via inhalation exhibit pulmonary effects which may last long after exposure ceases.

The following is a profile of the fate of beryllium in soil, surface water and sediment, and the fate after uptake by biological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

Beryllium adsorbs to clays at low pH, precipitates as insoluble complexes at higher pH, and has limited solubility in soil (Callahan et al. 1979). Chemical reactions in soil transform one beryllium compound into another (ATSDR 1993). Reactions in soil include hydrolysis of soluble salts, anion exchange, and complexation with ligands such as humic substances (ATSDR 1993).

In water, beryllium is speciated often by hydrolysis in which soluble beryllium salts are hydrolyzed to form relatively insoluble beryllium hydroxide (Callahan et al. 1979). Beryllium is not volatilized from water (ATSDR 1993). Beryllium is retained in an insoluble and immobile form in sediment (EPA 1980).

### **3.0 ECOLOGICAL RECEPTORS**

Beryllium uptake from water is low, resulting in low bioconcentration rates (EPA 1980; Callahan et al. 1979). Biomagnification of beryllium in aquatic food chains does not occur (Fishbein 1981).

In mammals, beryllium compounds are absorbed primarily through the lung (ATSDR 1993). Beryllium is poorly absorbed from the gastrointestinal tract, and is not absorbed through intact skin to any significant degree

(ATSDR 1993). Beryllium is distributed to the liver, skeleton, tracheobronchial lymph nodes, and blood (Finch et al. 1990). Beryllium is not biotransformed, but soluble beryllium salts are partially converted to less soluble forms in the lung (Reeves and Vorwald 1967). Excretion is predominantly via the feces (Finch et al. 1990). Data regarding the amount of beryllium that reaches the site of action or assimilation efficiency were not located.

Information was not available on the fate of beryllium in birds.

Beryllium uptake by plants occurs when beryllium is present in the soluble form. The highest levels of beryllium are found in the roots, with lower levels in the stems and foliage (EPA 1985).

**BIS(2-ETHYLHEXYL)PHTHALATE**

**1.0 SUMMARY**

Bis(2-ethylhexyl)phthalate (BEHP) is a high molecular weight, semi-volatile organic compound. BEHP adsorbs strongly to soil and sediment, and it may be biodegraded in aerobic environments. It has a low water solubility and low vapor pressure. It does not undergo significant photolysis, hydrolysis, or volatilization in soil or water. Receptors may be exposed to BEHP by the oral, inhalation, and dermal routes. BEHP bioconcentration in aquatic organisms is generally low, therefore significant food chain biomagnification in upper-trophic-level fish is unlikely. Mammalian and avian wildlife can metabolize and eliminate BEHP, therefore, it does not biomagnify in these receptors.

The following summarizes the fate of BEHP in surface soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate after released to surface soil, surface water, and sediment. Section 3 discusses the fate in ecological receptors.

**2.0 FATE IN SOIL, SURFACE WATER AND SEDIMENT**

BEHP adsorbs strongly to soil and does not undergo significant volatilization or photolysis (HSDB 1997). Limited information indicates that, under aerobic conditions, degradation in soil may occur (Hutchins et al. 1983; Mathur 1974). However, because BEHP adsorbs strongly to soil, biodegradation is slow (Wams 1987). Biodegradation in anaerobic conditions is slower than under aerobic conditions (Johnson et al. 1984).

BEHP has a low water solubility. In surface water environments, adsorption is the major mechanism affecting the concentration of BEHP. BEHP strongly adsorbs to suspended solids and sediments (Al-Omran and Preston 1987; Sullivan et al. 1982; Wolfe et al. 1980). However, in marine environments, adsorption to sediments may be decreased because BEHP is not as soluble in salt water when compared to fresh water (Al-Omran and Preston 1987). BEHP may also form complexes with fulvic acid, potentially increasing its mobility in aquatic environments (Johnson et al. 1977).

In aquatic environments, biodegradation is the primary route of degradation. BEHP is biodegraded in aerobic conditions; however, under anaerobic conditions, biodegradation is limited (O'Connor et al. 1989; Tabek et al. 1981; O'Grady et al. 1985). A half-life of approximately one month, due to microbial biodegradation has been reported for BEHP in river water (Wams 1987). BEHP does not undergo significant hydrolysis or photolysis in aquatic environments (Callahan et al. 1979). A hydrolysis half-life of 2,000 years has been estimated (Callahan et al. 1979); and in water a photolysis half-life of 143 days has been reported (Wolfe et al. 1980). BEHP does not significantly volatilize from water, with an half-life of 15 years reported (Callahan et al. 1979).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Aquatic receptors may be exposed through ingestion of contaminated food or water, dermal exposure, or in the case of fish, by direct contact of the gills with the surrounding water. Based on its low water solubility and high soil partition coefficient (ATSDR 1993), dietary uptake is the most significant route of exposure anticipated for BEHP.

Based on its high log Kow value, BEHP is expected to accumulate in aquatic species (Barrows et al. 1980; Mayer 1977). Invertebrates will bioconcentrate BEHP from surface water and from sediment. The level of bioconcentration is receptor-specific, because some invertebrates can metabolize BEHP, while some have limited capability (Sanders et al. 1973). Under continuous exposure conditions, fish will bioconcentrate BEHP to levels moderately higher than the concentration in surface water (Mehrle and Mayer 1976). BEHP has a short half-life in fish, indicating that it is quickly eliminated (Park et al. 1990). Fish eliminate BEHP by metabolizing it to polar byproducts, which are quickly excreted (Melancon and Lech 1977; Menzie 1980). Therefore, food chain accumulation and biomagnification of BEHP in aquatic food webs is not significant (Callahan et al. 1979; Johnson et al. 1977; Wofford et al. 1981).

BEHP is absorbed by mammals following oral (Astill 1989; Rhodes et al. 1986) or dermal exposure (Melnick et al. 1987), with oral exposure being the route with the greatest absorption efficiency in laboratory animals. In laboratory animals, small amounts of BEHP have been shown to be absorbed following dermal exposure (Melnick et al. 1987). Following oral exposure, it has been reported that a portion of the BEHP is hydrolyzed in the small intestine to 2-ethylhexanol and mono(ethylhexyl)phthalate

which is subsequently absorbed (Albro, et al. 1982). Following absorption, BEHP is distributed primarily to the liver and kidney, and in some species, to the testes (Rhodes et al. 1986).

In mammals, BEHP is metabolized by tissue esterases that hydrolyze one of the ester bonds resulting in the formation of mono(2-ethylhexyl)phthalate and 2-ethylhexanol. Small amounts of mono(2-ethylhexyl)phthalate may be further hydrolyzed to form phthalic acid; however, the majority undergoes aliphatic side chain oxidation followed by alpha- or beta-oxidation. These oxidized products may then be conjugated with glucuronic acid and excreted (Albro 1986). Metabolites of BEHP are excreted in both the urine and the feces (Astill 1989; Short et al. 1987; Ikeda et al. 1980).

BEHP may evaporate from the leaves of plants. In one study, using a closed terrestrial simulation chamber, BEHP was applied to the leaves of *Sinapis alba*. Evaporation rates from the leaves were <0.8 ng/cm<sup>2</sup>-hr for a time interval of 0–1 days and <0.5 ng/cm<sup>2</sup>-hr for a time interval of 8–15 days (Loekke and Bro-Rasmusen 1981). Uptake of BEHP by plants has also been reported (Overcash et al. 1986).

No data were available on the fate of BEHP in birds.

## **CADMIUM**

### **1.0 SUMMARY**

Cadmium exists in the elemental (0+) state or the 2+ valance state in nature. Exposure routes for aquatic organisms include ingestion and gill uptake. Freshwater biota are the most sensitive organisms to cadmium exposure, with toxicity inversely proportional to water hardness. Cadmium bioaccumulates in both aquatic and terrestrial animals, with higher bioconcentration in aquatic organisms. Exposure routes for ecological mammalian species include ingestion and inhalation. Cadmium interferes with the absorption and distribution of other metals and causes renal toxicity in vertebrates.

The following is a profile of the fate of cadmium in soil, surface water and sediment, and the fate after uptake by biological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER AND SEDIMENT**

Cadmium has a low vapor pressure and is released from soil to air by entrainment with soil particles (EPA 1980; OHM/TADS 1997). Cadmium compounds in soil are stable and are not subject to degradation (ATSDR 1993). Cadmium compounds can be transformed by precipitation, dissolution, complexation, and ion exchange (McComish and Ong 1988).

Cadmium compounds in aquatic environments are not affected by photolysis, volatilization, or biological methylation (Callahan et al. 1979). Precipitation and sorption to mineral surfaces and organic materials are important removal processes for cadmium compounds (ATSDR 1993). Concentrations of cadmium are generally higher in sediments than in overlying water (Callahan et al. 1979).

### **3.0 ECOLOGICAL RECEPTORS**

Cadmium bioconcentrates in aquatic organisms, primarily in the liver and kidney (EPA 1985). Cadmium accumulated from water is slowly excreted, while cadmium accumulated from food is eliminated more

rapidly (EPA 1985). Metal-binding, proteinaceous, metallothionens appear to protect vertebrates from deleterious effects of high metal body burdens (Eisler 1985).

Exposure routes in ecological mammalian species include ingestion and inhalation, while dermal absorption is negligible (Goodman and Gilman 1985). Absorption and retention of cadmium decreases with prolonged exposure. Cadmium absorption through ingestion is inversely proportional to intake of other metals, especially iron and calcium (Friberg 1979). Cadmium accumulates primarily in the liver and kidneys (IARC 1973). Cadmium crosses the placental barrier (Venugopal 1978). Cadmium does not undergo direct metabolic conversion, but the ionic (+2 valence) form binds to proteins and other molecules (Nordberg et al. 1985). Absorbed cadmium is excreted very slowly, with urinary and fecal excretion being approximately equal (Kjellstrom and Nordberg 1978).

Freshwater aquatic species are most sensitive to the toxic effects of cadmium, followed by marine organisms, birds, and mammals.

## **CHROMIUM**

### **1.0 SUMMARY**

Chromium exists primarily in the Cr<sup>3+</sup> and Cr<sup>6+</sup> valence forms in environmental and biological media. It exists in soil primarily in the form of insoluble oxides with very limited mobility. In the aquatic phase, chromium may be in the soluble state or attached to clay-like or organic suspended solids.

Exposure routes for aquatic organisms include ingestion, gill uptake, and dermal absorption. Bioaccumulation occurs in aquatic receptors; biomagnification does not occur in aquatic food chains. Exposure routes for ecological mammalian species include ingestion, inhalation, and dermal absorption. Chromium is not truly metabolized, but undergoes various changes in valence states and binding with ligands and reducing agents in vivo. Elimination of chromium is slow.

The following is a profile of the fate of chromium in soil, surface water and sediment, and the fate after uptake by biological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

In soil, chromium 3+ is readily hydrolyzed and precipitated as chromium hydroxide. It exists in soil primarily as insoluble oxide with very limited mobility (EPA 1984a, b).

In water, chromium 6+ occurs in the soluble state or as suspended solids adsorbed onto clay-like materials, organics, or iron oxides. Cr<sup>6+</sup> persists in water for long periods of time, but is eventually reduced to chromium 3+ by organic matter or other reducing agents in water (Cary 1982).

### **3.0 ECOLOGICAL RECEPTORS**

Exposure routes for aquatic organisms include ingestion, gill uptake, and dermal absorption. Chromium bioconcentrates in aquatic organisms (ATSDR 1993; OHM/TADS 1997; EPA 1985; EPA 1984a). The

biomagnification and toxicity of chromium 3+ is low relative to chromium 6+ because of its low membrane permeability and noncorrosivity. Chromium is not significantly biomagnified in aquatic food chains.

In vertebrates, chromium 3+ is an essential nutrient needed to produce glucose tolerance factor (GTF), which is required for regulation of glucose levels (ATSDR 1993). Exposure routes for ecological mammalian species include ingestion, inhalation, and dermal absorption. Chromium is poorly absorbed from the gastrointestinal tract after oral exposure, but fasting increases the absorption (Chen et al. 1973). Absorbed chromium is distributed to various organs including the liver and spleen (Maruyama 1982 as cited in ATSDR 1993; Witmer et al. 1989, 1991, as cited in ATSDR 1993).

Following inhalation exposure, chromium is distributed to the lung, kidney, spleen, and erythrocytes (Weber 1983; Baetjer et al. 1959). Following dermal exposure, chromium is readily absorbed and is distributed to the blood, spleen, bone marrow, lymph glands, urine, and kidneys. Chromium is not truly metabolized, but undergoes various changes in valence states and binding with ligands and reducing agents in vivo. Elimination of chromium is slow (Langard et al. 1978).

A large degree of accumulation by aquatic and terrestrial plants and animals in the lower trophic levels has been documented, however, the mechanism of this accumulation remains unknown.

## **COPPER**

### **1.0 SUMMARY**

Copper binds to soils and sediment. Copper is not biodegraded or transformed. Exposure routes for aquatic organisms include ingestion, gill uptake, and dermal absorption. In aquatic organisms, exposures to copper are associated with developmental abnormalities. Copper bioconcentrates in aquatic organisms, however, biomagnification does not occur. Exposure routes for ecological mammalian species include ingestion, inhalation, and dermal absorption. Copper is associated with adverse hematological, hepatic, developmental, immunological, and renal effects in mammals. Copper does not bioaccumulate in mammals.

The following is a profile of the fate of copper in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER AND SEDIMENT**

Copper occurs naturally in many animals and plants and is an essential micronutrient. Copper may exist in two oxidation states: +1 or +2. Copper (+1) is unstable and, in aerated water over the pH range of most natural waters (6 to 8), oxidizes to the +2 state. In the aquatic environment, the fate of copper is determined by the formation of complexes, especially with humic substances, and sorption to hydrous metal oxides, clays, and organic materials. The amount of copper able to remain in solution is directly dependent on water chemistry, especially pH and temperature, and the concentration of other chemical species (Callahan et al. 1979; Tyler and McBride 1982; Fuhrer 1986).

The majority of copper released to surface waters settles out or adsorbs to sediments (Harrison and Bishop 1984). Copper is affected by photolysis (Moffett and Zika 1987). Some copper complexes undergo metabolism however, biotransformation of copper is low (Callahan 1979).

### **3.0 ECOLOGICAL RECEPTORS**

Copper bioconcentrates in aquatic organisms. Copper does not biomagnify in aquatic food chains (Heit and Klusek 1985; Perwack et al. 1980).

Copper is absorbed by mammals following ingestion, inhalation, and dermal exposure (Batsura 1969; Van Campen and Mitchell 1965; Crampton et al. 1965). Once absorbed, copper is distributed to the liver (Marceau et al. 1970). Copper is not metabolized. Copper exerts its toxic effects by binding to DNA (Sideris et al. 1988) or by generating free radicals (EPA 1985). Copper does not bioaccumulate in mammals and is excreted primarily in the bile (Bush et al. 1955).

Copper is known to inhibit photosynthesis and plant growth. Because copper is an essential micronutrient for plant nutrition, most adverse effects result from copper deficiency (Adriano 1986).

## **CROTONALDEHYDE**

### **1.0 SUMMARY**

Crotonaldehyde is a highly volatile, water-soluble, low molecular weight, organic compound. Volatilization is the major fate process for crotonaldehyde in surface water and surface soil. Crotonaldehyde does not bioconcentrate in aquatic organisms and does not accumulate in wildlife. Therefore, food chain transfer is insignificant.

The following summarizes information about the fate of crotonaldehyde in soil, surface water, and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

Crotonaldehyde has a low  $K_{oc}$  value, therefore it will not strongly adsorb to soils (Irwin 1988 as cited in ATSDR 1990), and may dissolve in soil water. Crotonaldehyde has a short half-life (Lyman 1982) and it will quickly volatilize from surface soils.

Crotonaldehyde is completely miscible in water and does not dissolve in oils. However, based on its volatilization half-life of about 1 to 2 days (Bowmer et al. 1974; Thomas 1982), crotonaldehyde is expected to quickly volatilize from surface water. The adsorption of crotonaldehyde to suspended solids and sediment is not expected to be significant because of its low  $K_{oc}$  value (Lyman 1982).

Aerobic biodegradation may degrade crotonaldehyde at low concentrations in natural water (Bowmer and Higgins 1976; Callahan et al. 1979; Tabak et al. 1981). In addition, data suggest that persistence of crotonaldehyde in aerobic aquatic environments for moderate to long periods of time will not occur (Jacobson and Smith 1990 as cited in ATSDR 1990).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Based on its short volatilization half life and low bioconcentration factor (Bysshe 1982; Hansch and Leo 1985), crotonaldehyde will not concentrate in aquatic organisms.

Little information was available on the fate of crotonaldehyde in mammals. Because crotonaldehyde has a low soil adsorption coefficient and strongly volatilizes, inhalation is the primary exposure route for mammals. Studies have indicated that inhaled crotonaldehyde is quickly absorbed by the upper and lower respiratory tracts (Egle 1972). Studies also suggest that absorbed crotonaldehyde is quickly metabolized (Alarcon 1976; Kaye 1973; Patel et al. 1980).

No information was available on the fate of crotonaldehyde in birds or plants.

## **CUMENE (ISOPROPYLBENZENE)**

### **1.0 SUMMARY**

1-methylethylbenzene is also called cumene. Cumene and its superoxidized form, cumene hydroperoxide, are moderately volatile organic compounds. Cumene released to soil and surface water will rapidly dissipate through biodegradation and volatilization. Routes of exposure for cumene and cumene hydroperoxide include inhalation, ingestion, and dermal exposure. However, due to its high potential to volatilize, inhalation is the major exposure route for wildlife receptors. Bioconcentration of cumene is not likely in aquatic organisms. No information was available regarding the environmental fate of cumene hydroperoxide in air, water, or soil. However, degradation in soil and water is expected to be very rapid based on the high reactivity of cumene hydroperoxide with multivalent metal ions and free radicals.

The following is a profile of the fate of cumene and cumene hydroperoxide in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

The primary removal process for cumene in soil is expected to be through biodegradation in surface soil, and volatilization (HSDB 1997). Based on its log  $K_{oc}$  value (Lyman 1982), cumene that does not volatilize is expected to strongly adsorb to soil.

The environmental fate of cumene hydroperoxide in soil is unknown. However, based on its high reactivity with multivalent metal ions and free radicals, degradation in soil is expected to be very rapid (HSDB 1997).

In surface water, cumene is expected to have a relatively short half-life. The primary removal processes for cumene when released in water are volatilization and biodegradation (GEMS 1986; HSDB 1997). Based on different water characteristics, volatilization half-lives ranging from a few hours to a few days have been estimated (GEMS 1986). Cumene is amenable to biodegradation (Price et al. 1974; Kappeler and Wuhrmann 1978), and biodegrades in 10 to 30 days (Walker and Colwell 1975; Price et al. 1974).

The environmental fate of cumene hydroperoxide in water is unknown. However, based on its high reactivity with multivalent metal ions and free radicals, degradation in water is expected to be very rapid (HSDB 1997).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Cumene is reported to have relatively low bioconcentration in fish (ITC/EPA 1984; Geiger 1986;).

In wildlife, cumene and cumene hydroperoxide enter the body primarily via inhalation and dermal absorption (Lefaux 1968; HSDB 1997). Cumene is readily absorbed in mammalian systems and oxidized (Clayton and Clayton 1982). In the event that cumene is ingested, it is readily metabolized and excreted (Robinson et al. 1955). Long-term exposure by mammals results in cumene distribution to many tissues and organs (Gorban et al. 1978).

## **DDE**

### **1.0 SUMMARY**

Dichlorodiphenyldichloroethane (DDE) is a high molecular weight, chlorinated pesticide. It is also a congener of dichlorodiphenyltrichloroethane (DDT), a full-spectrum pesticide. DDE is stable, accumulates in soil and sediment, and concentrates in fatty tissue. DDE has a low water solubility, and is adsorbed strongly in soils and sediments. Soil and benthic organisms accumulate DDE from soil and sediment. Wildlife will accumulate DDE in fatty tissue. Following chronic exposure by wildlife to DDE, an equilibrium between absorption and excretion may occur; however, concentrations will continue to increase because accumulation is related to fat content, which increases with age.

The following summarizes the fate of DDE in surface soil, surface water, and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water, and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

DDE absorbs strongly to soil and is only slightly soluble in water. Under normal environmental conditions, DDE does not hydrolyze or biodegrade. In soils with low organic content, evaporation from the surface of soil may be significant (HSDB 1997).

DDE is bioavailable to plants and soil invertebrates despite being highly bound to soil. DDT has been found to accumulate in grain, maize, and rice plants with the majority located in the roots. Mobilization of soil-bound DDT by earthworms to more bioavailable forms has also been reported (Verma and Pillai 1991).

DDE is very persistent in the aquatic environment, has a very low water solubility, and is highly soluble in lipids. Compounds with these characteristics tend to partition to the organic carbon fraction of sediments and lipid fraction of biota (EPA 1986). DDE absorbs very strongly to sediment, and bioconcentrates in aquatic organisms (HSDB 1997). In aquatic environments, the small fraction of dissolved DDE may be photolyzed.

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

In general, DDE will bioconcentrate in lower-trophic-level organisms and will accumulate in food chains. Fish and other aquatic organisms readily take up pesticides, including DDE. Pesticides are taken up by organisms through the gills, by direct contact with the contaminant in the water, or by ingestion of contaminated food, sediment, or water. The lipophilic nature and extremely long half life of DDE result in bioaccumulation when it is present in ambient water. DDE will bioconcentrate in freshwater and marine plankton, insects, mollusks and other invertebrates, and fish (Oliver and Niimi 1985). When these organisms are consumed by other receptors, DDE is transferred up food chains. Following absorption, either through the gills or by ingestion, pesticides appear in the blood and may be distributed to tissues of all soft organs (Nimmo 1985).

DDE is accumulated to high concentrations in fatty tissues of carnivorous receptors. Elimination and absorption of DDE may occur simultaneously once an equilibrium is reached. This equilibrium may be disturbed by high concentrations of DDE, but termination of exposure usually results in elimination of the stored substance. This elimination occurs in two phases—an initial rapid phase followed by a much slower gradual loss (Nimmo 1985).

DDE can be introduced into mammals through oral, dermal, and inhalation exposure. Inhalation absorption is considered minor because the large particle size of DDE precludes entry to the deeper spaces of the lung; DDE is deposited in the upper respiratory tract and, through mucociliary action, is eventually swallowed and absorbed in the gastrointestinal tract. Gastrointestinal absorption following oral exposure has been shown in experimental animals (Hayes 1982). Dermal absorption is limited and the toxic effects are less than those seen following oral exposure. The highest concentration of DDE and metabolites has been found in adipose tissue, followed by reproductive organs, liver, kidneys, and brain (EPA 1980).

The metabolism of DDE in animals is similar to that in humans. DDE metabolism and elimination occurs very slowly. The primary route of elimination is in the urine (Gold and Brunk 1982, 1983, 1984); however, DDE may also be eliminated through the feces, semen, or breast milk. When exposure ceases, DDE is slowly eliminated from the body (Murphy 1986). The biological half-life of DDE is 8 years (NAS 1977).

Bioaccumulation has been reported in one Alaskan study of two raptor species—the Rough-legged hawk and the Peregrine falcon. Higher tissue residues were reported in the peregrine falcon than in the rough-legged hawk. It was believed that these differences may have been due to the different feeding habits of the birds (Matsumura 1985).

No information was available on the fate of DDE taken up by plants.

## **DICHLOROFLUOROMETHANE**

### **1.0 SUMMARY**

Dichlorofluoromethane (DCFM) is a highly volatile hydrocarbon. It has a high vapor pressure and low soil adsorption coefficient; therefore, volatilization is the main fate process for DCFM released to surface soil and surface water. For terrestrial animals, inhalation is the main exposure route and ingestion is a minor exposure route. DCFM is not expected to bioconcentrate in fish; however, it can accumulate in tissues of mammals. DCFM is not expected to move up food chains.

The following information summarizes the fate of dichlorofluoromethane in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

If released to soil, DCFM, an inert gas at room temperature, is expected to volatilize into the air due to its low soil adsorption coefficient ( $K_{oc}$ ) value (Lyman et al. 1982). Because it does not have a strong affinity for organic carbon, it may dissolve in soil pore water, thus becoming bioavailable. Photooxidation, hydrolysis, and biodegradation are not likely to be significant removal processes for DCFM in soil due to its high volatility and minimal reactivity (HSDB 1997).

Based on its high water solubility and low soil adsorption coefficient, DCFM does not adsorb strongly to suspended solids or sediment. Based on a reported half-life of less than 1 day, DCFM is expected to rapidly volatilize from water (Lyman et al. 1982). The hydrolysis of DCFM is reported to be very low (<0.01 g/l of water-yr) (Du Pont de Nemours Co. 1980).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

DCFM is not expected to bioconcentrate in aquatic organisms, based on its low  $\log K_{ow}$  value (Hansch and Leo 1985) and low estimated BCF value (Lyman et al. 1982).

Information was not available on the fate of DCFM in mammals, birds, or plants.

**DICHLOROETHENE, 1,1-**

**1.0 SUMMARY**

1,1-dichloroethene is a hydrophilic, low molecular weight, chlorinated hydrocarbon. It has a short half-life in the environment, thus acute exposures by ecological receptors are the main concern. Evaporation and biodegradation are major fate processes for 1,1-dichloroethene in soil, surface water, and sediment. It will also adsorb to detritus in soils and sediments. Ingestion and respiratory uptake are the significant direct exposure routes for ecological receptors exposed to 1,1-dichloroethene. Metabolic intermediates are responsible for the toxicity of 1,1-dichloroethene to upper trophic level receptors. Indirect (food chain) exposure through ingestion of contaminated food is minor because it is readily biotransformed and excreted. Hence, the biomagnification potential is very low.

The following is a profile of the fate of 1,1-dichloroethene in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

**2.0 FATE IN SOIL, SURFACE WATER AND SEDIMENT**

If released onto the soil surface, the majority of 1,1-dichloroethene will quickly evaporate. Depending on the hydrogeology of a site, some may leach into ground water. Based on its high water solubility and small  $K_{oc}$  value, 1,1-dichloroethene may migrate through soils by adsorbing to dissolved organic carbon (EPA 1982). Studies have also documented that 1,1-dichloroethene will biodegrade in soils (HSDB 1997). A bioaccumulation factor for 1,1-dichloroethene in soil was not reported. However, based on its volatility and polarity, 1,1-dichloroethene is not expected to significantly bioaccumulate in soil (Callahan et al. 1979).

Evaporation is the major fate of 1,1-dichloroethene in surface water, with a short half-life of 1-6 days. Only a small quantity of 1,1-dichloroethene will be lost by adsorption onto the sediment (HSDB 1997). 1,1-dichloroethene also quickly biodegrades in aqueous environments. Degradation studies showed that 45–78% was lost in 7 days, when incubated with a wastewater inoculum. A large amount was also lost due to volatilization (Patterson and Kodukala 1981). In anaerobic environments, 1,1-dichloroethene

degrades (through reductive dechlorination) to vinyl chloride. Anaerobic degradation is slower than aerobic degradation. Approximately 50-80% of 1,1-dichloroethene underwent degradation in 6 months in a simulated groundwater environment (Barrio-Lage et al. 1986; Hallen et al. 1986). Photo-oxidation and hydrolysis are not expected to be significant removal processes for 1,1-dichloroethene (Callahan et al. 1979; Mabey et al. 1981; Cline and Delfino 1987). A bioaccumulation factor for 1,1-dichloroethene in water and sediment was not reported. However, based on its volatility and polarity, 1,1-dichloroethene is not expected to significantly bioaccumulate in water or sediment (Callahan et al. 1979).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Aquatic receptors may be directly exposed to dissolved 1,1-dichloroethene through gill respiration or through ingestion of suspended particles. Because 1,1-dichloroethene generally is not persistent in surface water, exposures are expected to be of short duration. 1,1-dichloroethene is not expected to bioconcentrate in fish or aquatic invertebrates, based on its low log  $K_{ow}$  value (Tute 1971; HSDB 1997). Due to limited bioconcentration, 1,1-dichloroethene is not expected to biomagnify in terrestrial or aquatic food chains (Barrio-Lage et al. 1986; Wilson et al. 1986).

1,1-dichloroethene is readily absorbed following inhalation (Dallas et al. 1983; McKenna et al. 1978a) or oral exposure, and is rapidly distributed in the body. Following inhalation exposure to 1,1-dichloroethene, uptake is dependent upon the duration of the exposure and the dose. Until equilibrium is reached, as exposure concentration increases, the percentage of 1,1-dichloroethene uptake decreases. Studies show that 2 minutes after inhalation exposure, substantial amounts of 1,1-dichloroethene were found in the venous blood of rats. Concentrations of 150 ppm or less of 1,1-dichloroethene showed a linear cumulative uptake. However, at 300 ppm steady state was not achieved, indicating saturation at high concentrations (Dallas et al. 1983).

Following oral administration of 1,1-dichloroethene in corn oil, rapid and almost complete absorption from the gastrointestinal tract of rats and mice was observed (Jones and Hathway 1978a; Putcha et al. 1986). Recovery of radio-labeled 1,1-dichloroethene was 43.55, 53.88, and 42.11%, 72 hours following oral administrations of 0.5, 5.0, and 50 mg/kg, respectively, to rats (Reichert et al. 1979). Also, 14.9-22.6% 1,1 dichloroethene was recovered in expired air, 42.11-53.88% in urine, 7.65-15.74% in feces, 2.77-5.57% in the carcass, and 5.91-9.8% in the cage rinse (Reichert et al. 1979).

1,1-dichloroethene is distributed mainly to the liver and kidneys following inhalation or oral exposure. In rodents, the highest levels of 1,1-dichloroethene are found in the liver and kidneys. Rats that were fasted and exposed to 1,1-dichloroethene showed significantly greater tissue burden than nonfasted rats (McKenna et al. 1978b; Jones and Hathway 1978b).

1,1-dichloroethene does not appear to be stored or accumulated in tissues, but is metabolized by the hepatic microsomal cytochrome P-450 system. This reaction produces reactive intermediates responsible for the toxicity of 1,1-dichloroethene. These reactive intermediates are detoxified through hydroxylation or conjugation with GSH, which is the primary biotransformation pathway in the rat. Excretion of unmetabolized 1,1-dichloroethene is through exhaled air, and metabolites are excreted via urine and exhaled air (Fielder et al. 1985; ATSDR 1994).

Avian receptors may be directly exposed to 1,1-dichloroethene through the ingestion of surface water and soil. Absorption studies specific to avian species were not identified in the literature.

Data on the fate of 1,1-dichloroethene in plant receptors were not identified in the literature. However, based on the low probability of significant bioaccumulation, uptake by plant receptors is expected to be minimal.

## **DINITROTOLUENES**

### **1.0 SUMMARY**

2,4-dinitrotoluene and 2,6-dinitrotoluene are semi-volatile, nitrogen-substituted, organic compounds. They are moderately persistent in soil and have short half-lives in aqueous environments due to high rates of photolysis. Evidence also indicates that they are biodegraded in soil, surface waters and sediment. For wildlife, all routes of exposure are significant. Dinitrotoluenes are not expected to bioconcentrate in aquatic organisms and bioaccumulation is not expected in animal tissues. The major target organs following exposure to 2,4-dinitrotoluene are the liver and kidney. 2,6-dinitrotoluene is distributed to various organs following uptake. Evidence indicates that upper-trophic-level receptors rapidly metabolize 2,4-dinitrotoluene to innocuous by-products that are readily excreted. 2,6-dinitrotoluene is metabolized to a highly electrophilic ion that is capable of reacting with DNA and other biological nucleophiles.

The following summarizes the fate of 2,4-dinitrotoluene and 2,6-dinitrotoluene in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

2,4-dinitrotoluene is expected to be slightly mobile in soil, based on its estimated  $K_{oc}$  value (Lyman et al 1982; Kenaga 1980). Information on the biodegradation of 2,4-dinitrotoluene in soil was not located; however, biodegradation is thought to occur in both aerobic and anaerobic zones of soil, based on aqueous biodegradation experiments (HSDB 1997).

2,6-dinitrotoluene readily biodegrades when released into the soil. Half-lives of 73 and 92 days were reported, when tested in two soils, with degradation rates of 0.5 to 0.7 mg/kg/day reported (Loehr 1989). Based on the calculated  $K_{oc}$  value (Lyman et al. 1982) and the estimated log  $K_{ow}$  value (GEMS 1984), 2,6-dinitrotoluene is expected to be slightly mobile in soil (Kenaga 1980).

Volatilization of dinitrotoluenes from surface soil is expected to be negligible due to very low vapor pressures of these compounds (Banerjee et al. 1990). Hydrolysis is not a significant removal process for nitroaromatic hydrocarbons (Lyman et al. 1982).

2,4-dinitrotoluene and 2,6-dinitrotoluene have a slight tendency to sorb to sediments, suspended solids, and biota, based on measured log  $K_{ow}$  values (GEMS 1984). In surface water, photolysis is the primary removal process for 2,4-dinitrotoluene and 2,6-dinitrotoluene. Reported half-lives range from a few minutes to a few hours (Spanggord et al. 1980; Zepp et al. 1984). Hydrolysis is not a removal process for nitroaromatics (Lyman et al. 1982).

Dinitrotoluenes do not readily volatilize in surface water. Volatilization half-lives of 2,4-dinitrotoluene from distilled water were 248 and 133 hours, which correspond to the volatilization rate constants of 0.0028 and 0.0052/hour (Smith et al. 1981). Davis et al. (1981), reported a 0.3 percent loss of 2,6-dinitrotoluene in a model waste stabilization pond. Empirical evidence indicates that dinitrotoluenes are expected to biodegrade in surface waters (Uchimura and Kido 1987; Umeda et al. 1985; Kondo et al. 1988; Tabak et al. 1981).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Aquatic organisms take up 2,4-dinitrotoluene, however, it does not bioconcentrate because it is readily eliminated. Measured BCF values for dinitrotoluenes are low indicating that bioconcentration does not occur in aquatic organisms (Deneer et al. 1987; EPA 1980).

Evidence indicates that once it is ingested by wildlife, 2,4-dinitrotoluene is rapidly absorbed into the bloodstream (Rickert et al. 1983). 2,4-dinitrotoluene is quickly distributed, with the highest concentrations in the liver and kidney (Rickert and Long 1981). The metabolism of 2,4-dinitrotoluene occurs in the liver and the intestine (via intestinal microflora), and it is quickly eliminated through the urine and feces (Lee et al. 1978; Long and Rickert 1982; Rickert and Long 1981; Schut et al. 1983). Based on the low log P value for 2,4-dinitrotoluene, bioaccumulation in animal tissues is not expected (Callahan et al. 1979; Mabey et al. 1981).

Dinitrotoluenes are expected to be readily taken up by plants, based on structural analogies with 1,3-dinitrobenzene and p-nitrotoluene (McFarlane et al. 1987; Nolt 1988).

## **DI(N)OCTYLPHTHALATE**

### **1.0 SUMMARY**

Di(n)octylphthalate (DOP) is a high-molecular-weight, semi-volatile compound. It has a low water solubility and low vapor pressure, therefore it adsorbs strongly to the soil and sediment. Biodegradation is possible under aerobic conditions, but is slow under anaerobic conditions. DOP also undergoes hydrolysis in water. DOP may be absorbed following oral (dietary), inhalation, or dermal exposures, however dietary exposure is the most significant route of exposure. DOP may accumulate to increasing concentrations in algae, aquatic invertebrates, and fish, and accumulate to low levels in terrestrial wildlife. However, higher-trophic-level receptors will quickly metabolize it, therefore it does not biomagnify in food chains.

The following is a profile of the fate of DOP in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER AND SEDIMENT**

DOP has a very high  $K_{oc}$  value; therefore, it should adsorb strongly and remain immobile in soil (Wolf et al. 1980). Degradation in soil is slow, especially under anaerobic conditions (HSDB 1997).

Following release into aquatic environments, DOP adsorbs strongly to sediments and particulate material suspended in the water column (HSDB 1997). DOP has a moderate half-life in aquatic environments; losses are due to both volatilization and microbial degradation. Slow degradation is possible in aerobic conditions; however, DOP is resistant to anaerobic degradation (HSDB 1997). Approximately 50% degradation was observed within 5 days in a model terrestrial-aquatic ecosystem, with the monoester and phthalic acids the primary degradation products (Sanborn et al. 1975). DOP may bioconcentrate in aquatic organisms (Sanborn et al. 1975).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Sanborn et al. (1975) evaluated the bioconcentration and trophic transfer of DOP in model aquatic ecosystems containing phytoplankton, zooplankton, snails, insects, and fish. Evidence showed that the algae and invertebrates bioconcentrated DOP. Fish accumulated DOP to low levels, indicating that these receptors readily eliminate DOP.

DOP may be absorbed following oral, inhalation or dermal exposures (EPA 1980a); however, due to low volatility of DOP, inhalation is not a significant route of exposure (Meditext 1997). Following absorption, DOP is rapidly distributed with the highest amounts concentrated in the liver, kidney and bile (EPA 1980b). DOP is rapidly metabolized to water-soluble derivatives (Gosselin et al. 1984) prior to and after absorption (EPA 1980b). These metabolites are then excreted through the urine and the bile (Ikeda et al. 1978).

No information was available on the fate of DOP in birds or plants.

**DIOXANE, 1,4-**

**1.0 SUMMARY**

1,4-dioxane is a highly water-soluble, moderately volatile organic compound. In soil, surface water, and sediment environments, 1,4-dioxane is not persistent because it is volatile and because it has a low affinity for adsorption to organic carbon. It has a low potential to bioconcentrate in aquatic receptors. Wildlife can be exposed to 1,4-dioxane through ingestion, inhalation, and dermal contact. It does not bioaccumulate in food chains.

The following is a profile of the fate of 1,4-dioxane in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

**2.0 FATE IN SOIL, SURFACE WATER AND SEDIMENT**

Based on an estimated log  $K_{oc}$  value (Lyman et al. 1982), 1,4-dioxane is expected to have a low affinity for organic carbon in soil, thus having a high potential to leach out of surface soils (HSDB 1997). This reduces the exposure potential for vegetation (through root uptake) and soil invertebrates. In addition, because of its moderate vapor pressure, volatilization is expected to be a significant fate process in soil (Verschueren 1983). Based on the volatility of 1,4-dioxane, bioaccumulation is not considered to be a significant fate process in soil.

1,4-dioxane is infinitely soluble in water (Lange 1967). However, because 1,4-dioxane has a moderate vapor pressure at 25°C, volatilization from water is a significant removal process (Verschueren 1983; HSDB 1997). 1,4-dioxane is not expected to adsorb to suspended sediments or detritus due to the estimated  $K_{oc}$  value (HSDB 1997). Based on its high volatility in water and low absorption to sediments, bioaccumulation is not expected to be a significant fate process for 1,4-dioxane in water and sediment.

**3.0 FATE IN ECOLOGICAL RECEPTORS**

Because it is highly soluble in water, aquatic receptors can take up 1,4-dioxane through direct exposure, however, it is not expected to bioconcentrate based on its low  $K_{ow}$  value (Hansch and Leo 1985).

Information suggests that 1,4-dioxane has a low potential to be biodegraded in aerobic aquatic environments. Biodegradation experiments with activated sludge showed a negligible biochemical oxygen demand for 1,4-dioxane, therefore, classifying 1,4-dioxane as relatively undegradable (Mills 1954; Alexander 1973; Heukelekian and Rand 1955; Fincher and Payne 1962; Lyman et al. 1982; Kawasaki 1980).

No information was available on the fate of 1,4-dioxane after uptake by aquatic receptors. However, its low bioconcentration factor suggests that 1,4-dioxane is readily eliminated after uptake (Hansch 1985).

The metabolism of 1,4-dioxane in rats has been studied, and information indicates that at high daily doses, 1,4-dioxane can induce its own metabolism. There is an apparent threshold of toxic effects of 1,4-dioxane that coincides with saturation of the metabolic pathway for its detoxification (Young et al. 1978). 1,4-dioxane is highly toxic via all routes of exposure (OHM/TADS 1997), and is readily absorbed through intact skin (Gosselin 1984). Once 1,4-dioxane enters the body, it is distributed throughout the tissues, including the liver, kidney, spleen, lung, colon, and skeletal muscle (Woo et al. 1977). The excretion of 1,4-dioxane is primarily through the urine, in which approximately 85% of excreted material is in the form of beta-hydroxyethoxyacetic acid, a metabolic byproduct. The remaining material is excreted as unchanged dioxane (Braun & Young 1977).

Information was not available on the fate of 1,4-dioxane in birds or plants.

## **DIBENZO-*p*-DIOXINS**

### **1.0 SUMMARY**

Dibenzo-*p*-dioxins (dioxins) are a group of high molecular weight chlorinated compounds that are highly soluble in fatty tissues. The congener tetrachlorodibenzodioxin (TCDD) is commonly used as a surrogate for estimating the fate of dioxins in the environment and in ecological receptors. Dioxins have low water solubilities and adsorb strongly to organic carbon in sediment and soil. Dioxins bioaccumulate in aquatic organisms and wildlife, and biomagnify in food chains because of their affinity for lipids. Biomagnification of TCDD appears to be significant between fish and fish-eating birds, but not between fish and their food (other fish).

The following is a profile of the fate of dioxins in soil, surface water, and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water, and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

TCDD adsorbs strongly to soils (HSDB 1997). TCDD in soil may be susceptible to photodegradation. Volatilization from soil surfaces during warm months may be a major mechanism by which TCDD is removed from soil. Various biological screening studies have demonstrated that TCDD is generally resistant to biodegradation. The half-life of TCDD in surface soil varies from less than 1 year to 3 years. Half-lives in deeper soils may be as long as 12 years (EPA 1993).

TCDD is very persistent in the aquatic environment, has a very low aqueous solubility, and is highly soluble in lipids. Aquatic sediments are an important reservoir for dioxins, and may be the ultimate environmental sink for all global releases of TCDD (HSDB 1997). TCDD may be removed from water through either photolysis or volatilization. The photolysis half-life at surface level has been estimated to range from 21 hours in summer to 118 hours in winter (HSDB 1997). These rates increase significantly with increasing water depths. Therefore, many bottom sediments may not be susceptible to significant photodegradation. The volatilization half-life from the water column of an environmental pond has been estimated to be 46 days, and may be as high as 50 years if adjusted for the effects of sediment adsorption.

Various biological screening studies have demonstrated that TCDD is generally resistant to biodegradation. The persistent half-life of TCDD in lakes has been estimated to be in excess of 1.5 years (HSDB 1997).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Ecological exposures to TCDD can occur via ingestion of contaminated soils, water, and sediment, dermal exposure to soil and water, and to a much lesser extent via inhalation of airborne vapors and particulates. It should be noted that, unlike toxicokinetic and toxicodynamic studies where exposures are closely controlled, environmental exposure to dioxin occurs as a complex mixture of congeners, including TCDD. It is generally understood that persistent, lipophilic compounds accumulate in fish in proportion to the lipid content and age of each animal (Gutenmann et al. 1992). Also, it has been demonstrated that the influence of biotransformation on bioaccumulation increases as a function of the  $K_{ow}$  of the compound (de Wolf et al. 1992). The dependence of metabolic rate on TCDD dose and length of exposure is not well understood, but time-course studies of P-450 induction in rainbow trout by  $\beta$ -naphthoflavone demonstrate that different toxicity responses can occur over time depending on the frequency and duration of exposure (Zhang et al. 1990).

Dioxins readily bioconcentrate in aquatic organisms (Branson et al. 1985; Mehrle et al. 1988; Cook et al. 1991; and Schmieder et al. 1992). Evidence indicates that dioxins will distribute in fish tissues in proportion to the total lipid content of the tissues (Cook et al 1993). Dioxins are metabolized and eliminated very slowly from fish (Kleeman et al. 1986a,b; Opperhuizen and Sijm 1990; Kuehl et al. 1987).

Several studies in a wide range of mammalian and aquatic species indicate that TCDD is metabolized to more polar metabolites (Ramsey et al. 1979; Poiger and Schlatter 1979; Olson et al. 1980; Olson 1986; Poiger et al. 1982; Sijm et al. 1990; Kleeman et al. 1986a,b, 1988; Gasiewicz et al. 1983; Ramsey et al. 1982). The metabolism of TCDD and related compounds is required for urinary and biliary elimination and plays an important role in regulating the rate of excretion of these compounds.

Dioxins are transferred through food chains, biomagnifying in upper-trophic-level receptors, especially birds. Biomagnification of TCDD appears to be significant between fish and fish-eating birds but not between fish and their food (Carey et al. 1990). The lack of apparent biomagnification between fish and their prey is probably due to the influence of biotransformation of TCDD by the fish. Limited data for the

base of the Lake Ontario lake trout food chain indicates little or no biomagnification between zooplankton and forage fish (Whittle et al. 1992). BMFs based on fish consuming invertebrate species probably are close to 1.0 because of the TCDD biotransformation by forage fish.

Oral absorption of dioxin related compounds in laboratory animals has been reported to be contingent on species, test compound, administered dose, and vehicle. Typical oral absorption values range from 50 to 90 percent (EPA 1994). Because TCDD in the environment is likely to be adsorbed strongly to soil, the oral bioavailability of TCDD varies significantly from laboratory values. Studies have shown that oral bioavailability of TCDD in soil is lower by as much as 50 percent as compared to oral bioavailability of TCDD administered in corn oil over a 500-fold dose range (EPA 1994). Moreover, oral bioavailability of TCDD may be significantly lower in different soil types, with values as low as 0.5 percent bioavailability reported (Umbreit et al. 1986 a,b).

Dermal absorption of TCDD has been studied extensively in laboratory animals. Dermal absorption has been demonstrated to depend on applied dose, with lower relative absorption (percentage of administered dose ) decreasing at higher doses (Brewster et al. 1989). Dermal absorption rates in laboratory rats ranged from 17 to 40 percent of administered dose (Brewster et al. 1989). Percent bioavailability of TCDD following dermal absorption is significantly lower than bioavailability following oral absorption by as much as 60 percent (Poiger and Schlatter 1980). As with oral absorption of TCDD in soil, percent bioavailability following dermal exposure to TCDD in soil was significantly lower than percent bioavailability following an equivalent oral dose (approximately 1 percent of an administered dose) (Shu et al. 1988).

Transpulmonary absorption of TCDD has been studied in laboratory animals following intratracheal instillation of the compound in various vehicles (Nessel et al. 1990, 1992). Systemic effects characteristic of TCDD exposures, including hepatic microsomal cytochrome p-450 induction, were observed after inhalation exposures, indicating that transpulmonary absorption does occur and that inhalation may be an important route of TCDD exposure. Transpulmonary bioavailability was estimated at approximately 92 percent of administered dose, very similar to that observed after oral exposures (Diliberto et al. 1992). It should be noted that in an environmental setting, inhalation exposures to TCDD in fly ash, dust and soil particulates may be associated with very different absorption and bioavailability patterns.

Tissue distribution studies in laboratory rats and mice indicate that TCDD is distributed preferentially to adipose tissue and liver (EPA 1994). TCDD is distributed to other organs as well, but to a lesser extent. Also, tissue distribution of TCDD has been demonstrated to be time and dose-dependent, with increasing levels of TCDD distributing to adipose and liver associated with higher doses and increased latency period from time of dosage (EPA 1994).

Plants will take up TCDD through root uptake from soil and through foliar uptake from air (EPA 1994). No other information was available on the fate of dioxins after uptake by plants.

No information was available on the fate of dioxins in birds.

## **DIBENZOFURANS**

### **1.0 SUMMARY**

Polychlorinated dibenzofurans (PCDF) are a class of hydrophobic chlorinated compounds that adsorb strongly to soils and sediments. Like dioxins, PCDFs are persistent in the environment, bioconcentrate in aquatic organisms, and biomagnify in some food chains. Because PCDFs are associated with organic material in abiotic media, direct contact by soil and sediment receptors, and ingestion by bottom-feeding fish and upper trophic level wildlife, are the most important exposure routes.

Since PCDFs are structurally similar to, and behave in the environment like dioxins, fate of PCDFs is inferred from information about dioxins. Most of the description on the fate of PCDFs is based on the behavior of tetrachlorodibenzofuran (TCDF), one of the most toxic PCDF congeners. The following is a profile of the fate of polychlorinated dibenzofurans (PCDFs) in soil, water, and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water, and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

TCDF adsorbs strongly to soils. Based upon its high  $K_{oc}$  value, TCDF is expected to sorb very strongly in soil and not be susceptible to leaching under most soil conditions. No data are available regarding the biological degradation of TCDF in soil (HSDB 1997).

TCDF in the water column can be expected to partition strongly to sediment and suspended particulate matter. Volatilization from the water column can be important, however the significance of this fate process is limited by strong sorption to sediments (HSDB 1997). Bioconcentration in aquatic organisms may be significant. Aquatic hydrolysis is not expected to be important. Data on biodegradation of TCDF are unavailable (HSDB 1997).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Based on high Kow values, PCDFs are expected to accumulate in aquatic receptors (Gutenmann et al. 1992).

Based on its similar structure to dioxins, PCDFs are expected to accumulate to high concentrations in aquatic and semi-aquatic mammals and in fish-eating birds.

Information was not available on the disposition of PCDFs in plants.

## **HEXACHLOROBENZENE**

### **1.0 SUMMARY**

Hexachlorobenzene (HCB) is a persistent chemical that adsorbs strongly to soil and sediment. It is relatively stable in the environment and is resistant to hydrolysis, photolysis, and oxidation, with relatively no metabolism by microorganisms. Due to its high affinity for organic carbon, HCB will accumulate in sediments. Soil invertebrates and benthic invertebrates will take up HCB directly from these media. For higher-trophic-level receptors, indirect (food chain) exposure is anticipated to be the most significant pathway because HCB is resistant to metabolism and is very soluble in fat. The major toxic effect that has been observed across all species tested is porphyria.

The following is a profile of the fate of HCB in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

Due to a long half-life in soil and its strong affinity for organic carbon, HCB released to soil is likely to remain there for extended periods of time (Beck and Hansen 1974). Minimal biodegradation occurs, depending on the organic carbon content of the soil. Some evaporation from surface soil to air may occur, again depending on the organic carbon content of the soil (Gile and Gillett 1979).

Once released to water, HCB will either evaporate rapidly or adsorb to sediments, with very little dissolved in water (HSDB 1997; Kelly et al. 1991). Limited degradation of HCB is expected, since it appears to be stable to hydrolysis, photolysis, and oxidation (Callahan et al. 1979). Since HCB adsorbs strongly to sediments, it may build up in bottom sediments.

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Aquatic organisms may be exposed to HCB through ingestion of contaminated water, soil, sediment, or food. Empirical information indicates that HCB bioconcentrates in fish and invertebrates (Giam et al.

1980; Konemann and Vanleeuwen 1980; Veith et al. 1979; Oliver and Niimi 1983; Parrish et al. 1978; Kosian et al. 1978; Neely et al. 1974; Zitko and Hutzinger 1976; Laseter et al. 1976).

HCB can be transferred through aquatic food chains. Knezovich and Harrison (1988) reported that chironomid larvae, a common food item of young fish and other aquatic receptors, rapidly bioaccumulate HCB and other chlorobenzenes from contaminated sediments, achieving steady state within 48 hours. Information was not available about metabolism of HCB by fish.

Ingestion of contaminated media and food is the main route of mammalian exposure to HCB (HSDB 1997; ATSDR 1994; Edwards et al. 1991). Following ingestion, HCB is readily absorbed and is distributed through the lymphatic system to all tissues. It accumulates in fatty tissues and persists for many years since it is highly lipophilic and is very slowly metabolized (Weisenberg 1986; Mathews 1986).

HCB is slowly metabolized by the hepatic cytochrome P-450 system, conjugated with glutathione, or reductively dechlorinated (ATSDR 1994). The metabolites of HCB in laboratory animals include pentachlorophenol, pentachlorobenzene, tetrachlorobenzene, traces of trichlorophenol, a number of sulfur containing compounds, and some unidentified compounds (Mehendale et al. 1975; Renner and Schuster 1977, 1978; Renner et al. 1978; Edwards et al. 1991).

Plants take up relatively minimal amounts of HCB from soils (EPA 1985; Carey et al. 1979). Information was not available on the fate of HCB in birds.

## **HEXACHLOROBUTADIENE**

### **1.0 SUMMARY**

Hexachlorobutadiene (HCBD) is a moderately volatile, high molecular weight, chlorinated compound. In surface soil and sediment, it will adsorb to organic carbon. It is moderately soluble in water. In surface water, it will adsorb to suspended material; however, it has a tendency to volatilize. In aerobic environments, it will biodegrade. Exposure routes for aquatic organisms include ingestion, gill uptake, and dermal contact. HCBD bioconcentrates in aquatic life. For mammalian and avian wildlife, HCBD can be taken up through oral, inhalation, and dermal exposure routes. HCBD is not expected to bioaccumulate to high levels in upper-trophic-level receptors. HCBD metabolites cause adverse effects.

The following is a profile of the fate of HCBD in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

HCBD has a high soil partition coefficient, and would, therefore, be expected to adsorb to soils with a high organic content (Montgomery and Welkom 1990); however, in sandy soils with a low organic content, HCBD is more mobile and will be found in soil pore water (Piet and Zoeteman 1980). HCBD also has a moderate potential to evaporate from surface soils, unless it is bound to organic carbon (Pearson and McConnell 1975). HCBD is expected to biodegrade in aerobic soils (Tabak et al. 1981), but not in anaerobic environments (Johnson and Young 1983).

Following release into water, HCBD will either quickly volatilize or adsorb to sediments and suspended material (Montgomery and Welkom 1990). HCBD will accumulate concentrations in sediments (Elder et al. 1981; EPA 1976; Oliver and Charlton 1984). Biodegradation is a significant removal process for HCBD in aerobic environments (Tabak et al. 1981). However, under anaerobic conditions biodegradation does not occur (Johnson and Young 1983).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

HCBD dissolved in surface water is expected to bioconcentrate in aquatic organisms, including algae, benthic macroinvertebrates (such as worms and bivalves), detritivore (crayfish), and plantivorous fish (EPA 1976, Oliver and Niimi 1983). HCBD also accumulates in carnivorous fish (EPA 1976). In fish, HCBD will distribute to fatty tissue, especially the liver (Pearson and McConnell 1975 as cited in ATSDR 1994).

Mammals may be exposed to HCBD through (1) ingestion of soil and exposed sediment while foraging for food, grooming, and soil covering plant matter, (2) ingestion of drinking water, and (3) indirect ingestion of contaminated plant and animal matter. Based on HCBD's affinity for soil and sediment, and its potential to be bioconcentrated, it is anticipated that indirect exposure will be the most significant exposure route for mammals. Once ingested, HCBD is readily absorbed in the gastrointestinal tract (Reichert et al. 1985). Following absorption, HCBD is distributed primarily to the kidney, liver, adipose tissue, and brain (Dekant et al. 1988; Nash et al. 1984; Reichert et al. 1985).

HCBD does not appear to be metabolized by the hepatic mixed function oxidase system; however, it does undergo conjugation with glutathione in the liver (Garle and Fry 1989). Metabolic derivatives of these conjugates are believed to be responsible for the renal damage associated with exposure to HCBD (Dekant et al. 1991; Koob and Dekant 1992).

In gravid birds, low levels of HCBD will be transferred to eggs (Dow Chemical Co. 1972).

Information was not available on the fate of HCBD in plants.

## **HEXACHLOROCYCLOPENTADIENE**

### **1.0 SUMMARY**

Hexachlorocyclopentadiene (HCCP) is a semi-volatile, chlorinated compound. If HCCP is released as an emission product, it has been shown to exist mostly in the vapor phase, with photolysis resulting in rapid degradation. HCCP in soil will adsorb to soil particles. Degradation of HCCP may also occur in the environment by chemical hydrolysis and biodegradation by soil biota. Depending on the route of exposure, HCCP may distribute mainly to the lungs, kidneys, and liver. HCCP could potentially bioaccumulate in some aquatic organisms depending upon the species. The respiratory system is the major site of toxicity following inhalation exposure, while, depending on the species, the kidney or the liver are the major sites of toxicity following oral exposure.

The following is a profile of the fate of HCCP in soil, surface water and sediment, and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

HCCP deposited to soil is expected to adsorb strongly to organic carbon in the soil (HSDB 1997). Volatilization from soil surfaces is expected to be minor. In moist soil, hydrolysis and biodegradation under aerobic and anaerobic conditions may occur (HSDB 1997). HCCP on the surface of soil may be subject to photolysis.

HCCP present in surface water will degrade primarily by photolysis and chemical hydrolysis. The half-life of HCCP from photodegradation is very short ; Wolfe et al.(1982) reported a half-life of less than 15 minutes in the top of the water column. In unlit or deep, turbid water, the degradation of HCCP occurs by chemical hydrolysis. Hydrolytic half-lives for HCCP range from several hours to 2-3 weeks, depending on the temperature of the water (Chou et al. 1981; Zepp and Wolfe 1987). HCCP has the potential to adsorb to suspended solids in surface water and sediments; however, this adsorption does not affect the rate of hydrolysis (Wolfe et al. 1982).

Volatilization from water is also expected to be a significant removal mechanism; however, adsorption to suspended solids and sediments may interfere with this process. (EPA 1987).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

HCCP is expected to be moderately bioconcentrated by algae, invertebrates, and fish. (Lu et al. 1975; Spehar et al. 1979; Veith et al. 1979; Podowski and Khan 1984; Freitag et al. 1982) (Geyer et al. 1981). HCCP taken up by freshwater fish (goldfish) is readily distributed, stored, and metabolized (Podowski et al. 1991). In fish, HCCP is excreted in the bile. The biological half-life of HCCP in the goldfish was approximately 9 days (Podowski and Khan 1984).

Inhalation is the main exposure route for HCCP toxicity in mammals. HCCP is less absorbed following ingestion (Lawrence and Dorough 1981). Following ingestion, HCCP will move primarily to the liver and the kidney (Lawrence and Dorough 1981), which appear to be the main sites of toxicity (Abdo et al. 1984; Southern Research Inst 1981).

Limited information was available regarding the metabolism of HCCP. Some degradation may occur in the gut following oral administration (Dorough and Ranieri 1984; Mehendale 1977).

Information was not available on the fate of HCCP in birds or plants.

## **HEXACHLOROPHENE**

### **1.0 SUMMARY**

Hexachlorophene is a persistent organic chemical that is highly soluble in lipids and adsorbs strongly to soil and sediment. In surface soils and the euphotic (light-penetrating) zone of surface waters, hexachlorophene is degraded by photolysis. Hexachlorophene may be bioconcentrated by aquatic and soil organisms. In upper-trophic-level receptors, hexachlorophene may be absorbed following oral or dermal exposure and is distributed throughout all body tissues. Due to its high lipid solubility, hexachlorophene has the potential to be transferred significantly in food chains. In mammals, the nervous system is the major site of toxicity for hexachlorophene; however, reproductive and developmental effects have also been reported. Exposure to hexachlorophene may result in decreased egg production in birds.

The following is a profile of the fate of hexachlorophene in soil, surface water, and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water, and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

Hexachlorophene adsorbs strongly to soil and once bound does not tend to leach from soil or mobilize in soil. Hexachlorophene does not undergo significant hydrolysis or evaporation from the soil; however, slow photodegradation may occur if exposed to light above 290 nm (Kotzias et al. 1982).

Hexachlorophene does not undergo hydrolysis, evaporation or volatilization in water; however, slow photodegradation may occur. Hexachlorophene adsorbs strongly to sediments and has been identified in the humic acid portion of sediment. The half-life of hexachlorophene in water is expected to be greater than 50 years with a half-life of 290 days reported in sediment. Hexachlorophene has been reported to bioconcentrate in aquatic organisms (Kotzias et al. 1982; Hansch and Leo 1985; Lyman et al. 1982).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Based on its high octanol-water partition coefficient, hexachlorophene is expected to bioconcentrate in aquatic life living in the water column and in the sediment. Bioconcentration has been measured in mosquito fish and snail (Hansch and Leo 1985; Lyman et al. 1982).

Hexachlorophene is absorbed rapidly following oral exposure (Hatch 1982). Hexachlorophene may also be absorbed following dermal exposure with blood levels peaking approximately 6 to 10 hours post-application (Meditext 1997). Hexachlorophene is highly lipid-soluble. After entering the bloodstream, it distributes into adipose tissue and tissue with a high lipid content including the central nervous system. Hexachlorophene binds preferentially to myelin (Meditext 1997). Transplacental transfer of hexachlorophene has also been reported (Hatch 1982). Target organs include the nervous system, the gastrointestinal system, and skin (Meditext 1997).

Hexachlorophene has been reported to have low volatility from plant leaves (Goetchius et al. 1986). Additional data regarding the potential effects of hexachlorophene on plants were not located. Information was not available on the fate of hexachlorophene in exposed birds.

## **HYDRAZINE**

### **1.0 SUMMARY**

Hydrazine is a reactive, nitrogen-containing compound. It is readily biodegraded after release to soil and surface water. Volatilization may also be a significant removal process. Hydrazine is readily absorbed following inhalation, ingestion, and dermal absorption. Mammals rapidly break down and excrete hydrazine.

The following is a profile of the fate of hydrazine in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water, and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

Studies show that hydrazine is expected to biodegrade in soils high in organic carbon, and to adsorb to soils high in clay content (Braun and Zirrolli 1983; Sun et al. 1992). For dry surface soil, volatilization may be a significant process (HSDB 1997).

Hydrazine is expected to have a relatively short half-life of 8.3 days in pond water (Braun and Zirrolli 1983). Hydrazine has been reported to react with dissolved oxygen at a rate inversely proportional to its concentration (Slonim and Gisclard 1976); its degradation rate increases with increasing temperature, dissolved oxygen, and the presence of microorganisms (Sun et al. 1992).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Hydrazine is absorbed rapidly from the lungs, gastrointestinal tract, and through skin (ACGIH 1991). Hydrazine is reported to be neurotoxic, hepatotoxic and nephrotoxic in rodents (Lambert and Shank 1988). Hydrazine is rapidly metabolized in the liver and eliminated (Jenner and Timbrell 1995).

Information was not available on the fate of hydrazine in exposed birds, aquatic life, or plants.

## **MERCURY**

### **1.0 SUMMARY**

Mercury is a highly toxic compound with no known natural biological function. Mercury exists in three valence states: mercuric ( $\text{Hg}^{2+}$ ), mercurous ( $\text{Hg}^{1+}$ ), and elemental ( $\text{Hg}^0$ ) mercury. It is present in the environment in inorganic and organic forms. Inorganic mercury compounds are less toxic than organomercury compounds, however, the inorganic forms are readily converted to organic forms by bacteria commonly present in the environment. The organomercury compound of greatest concern is methylmercury.

Mercury sorbs strongly to soil and sediment. Elemental mercury is highly volatile. In aquatic organisms, mercury is primarily absorbed through the gills. In aquatic and terrestrial receptors, some forms of mercury, especially organomercury compounds, bioaccumulate significantly and biomagnify in the food chain. In all receptors, the target organs are the kidney and central nervous system. However, mercury causes numerous other effects including teratogenicity and mutagenicity.

The following is a profile of the fate of mercury in soil, surface water and sediment, and the fate after uptake by biological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

In soil, mercury exists in the mercuric ( $\text{Hg}^{2+}$ ) and mercurous ( $\text{Hg}^{1+}$ ) states. Mercury adsorbs to soil or is converted to volatile forms (Krabbenhoft and Babiarz 1992; Callahan et al. 1979). Mercury can migrate by volatilization from aquatic and terrestrial sources through the reduction of metallic mercury to complex species and by the deposition in reducing sediments. Atmospheric transport is a major environmental distribution pathway.

Mercury  $2^{+}$  is the predominant form of mercury in surface waters (ATSDR 1993). Nonvolatile mercury in surface water binds to organic matter and sediment particles (Lee and Iverfeldt 1991).

Sorption to suspended and bed sediments is one of the most important processes determining the fate of mercury in aquatic systems; sorption onto organic materials is the strongest for mercury 2+. As a result, mercury is generally complexed to organic compounds and is not readily leached from either organic-rich or mineral-rich soils (Rosenblatt et al 1975). Most mercury compounds can be remobilized in aquatic systems by microbial conversion to methyl and dimethyl forms. Conditions reported to enhance microbial conversion include large amounts of available mercury, large numbers of bacteria, absence of strong complexing agents, near neutral pH, high temperatures, and moderately aerobic conditions.

### **3.0 ECOLOGICAL RECEPTORS**

Sorption at the gill surface is the major pathway of mercury entry in aquatic organisms (EPA 1984). In aquatic organisms, bioaccumulation is rapid and elimination is slow. Biomagnification occurs in the aquatic food chain (NRCC 1979). Absorbed mercury is distributed to the blood and ultimately the internal organs. Mercury which is not absorbed is eliminated rapidly in the feces (Eisler 1987). The biological half-life of mercury in fish is approximately 2 to 3 years (EPA 1985). In general, mercury accumulation is enhanced by elevated water temperatures, reduced water hardness or salinity, reduced water pH, increased age of the organism, reduced organic matter content of the medium, and the presence of zinc, cadmium, or selenium in solution.

Mercury is readily absorbed by terrestrial species following oral and inhalation exposure. Elemental and organomercury compounds are readily transferred across the placenta and blood-brain barrier. Mercury is bioaccumulated primarily in the kidney (Rothstein and Hayes 1964; Nielsen and Andersen 1991), and mercury is biomagnified in mammals (Eisler 1987). Retention of mercury in mammals is longer for organomercury compounds (especially methylmercury) than for inorganic forms. Mercury elimination occurs via the urine, feces, expired air, and breast milk (Clarkson 1989; Yoshida et al. 1992).

All mercury compounds interfere with metabolism in organisms, causing inhibition or inactivation of proteins containing thiol ligands and ultimately leading to mitotic disturbances (Das et al 1982; Elhassani 1983). Mercury also binds strongly with sulfhydryl groups. Phenyl and methyl mercury compounds are among the strongest known inhibitors of cell division (Birge et al 1979). In mammals, methyl mercury irreversibly destroys the neurons of the central nervous system.

Information was not available on the fate of mercury in birds.

Mercury in soils is generally not available for uptake by plants due to the high binding capacity to clays and other charged particles (Beauford et al 1977). However, mercury levels in plant tissues increase as soil levels increase with 95% of the accumulation and retention in the root system (Beauford et al 1977; Cocking et al 1991). Mercury is reported to inhibit protein synthesis in plant leaves and may affect water-adsorbing and transporting mechanisms in plants (Adriano 1986).

## **METHANOL**

### **1.0 SUMMARY**

Methanol is a highly water soluble hydrocarbon. It does not adsorb to organic carbon. The primary removal process for methanol in soil and water is biodegradation. Aquatic, soil, and sediment communities can be exposed to methanol through direct contact. Upper-trophic-level receptors may be directly exposed through ingestion, inhalation, or dermal exposure. Methanol does not bioconcentrate or move through food chains.

The following is a profile of the fate of methanol in soil, surface water, and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water, and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

Based on biological screening studies, including soil microcosm studies, methanol undergoes biodegradation if released to the soil. Methanol is expected to be highly mobile in soil, based on its miscibility in water and low log  $K_{ow}$  value. Evaporation from dry surfaces is also expected to occur, based on the high vapor pressure of methanol (Weber et al. 1981; Hansch and Leo 1985; HSDB 1997).

Methanol is completely soluble in water. Methanol is significantly biodegradable in water, based on screening studies (HSDB 1997). Volatilization is expected to be a significant removal process (Lyman 1982). Aquatic hydrolysis, oxidation, photolysis, adsorption to sediment, and bioconcentration are not considered significant removal processes for methanol (HSDB 1997).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Methanol uptake across gill epithelia is the most significant exposure route. However, based on its low bioconcentration factor for fish, methanol does not bioconcentrate (Freitag et al. 1985; Bysshe 1982) (Hansch and Leo 1985).

Mammals are exposed to methanol through ingestion, inhalation, and dermal contact. Methanol is reported to readily absorb from the gastrointestinal and respiratory tracts (Gosselin et al. 1984), and rapidly distribute within tissues (Clayton and Clayton 1982). Following absorption, methanol is widely distributed in body tissue. Small amounts are excreted in the urine and expired air; however, methanol is mostly oxidized to formaldehyde and formic acid (Goodman and Gillman 1985).

Information was not available on the fate of methanol in exposed birds or plants.

## **NITROPROPANE, 2-**

### **1.0 SUMMARY**

2-nitropropane is a highly volatile, low molecular weight hydrocarbon. Generally, it does not adsorb to soil or sediment, and rapidly volatilizes from soil and surface water. Wildlife may be exposed to 2-nitropropane through ingestion or inhalation. Due to its high water solubility, 2-nitropropane does not bioconcentrate in fish, and does not bioaccumulate in wildlife. 2-nitropropane is rapidly metabolized and excreted by mammals.

The following summarizes information on the fate of 2-nitropropane in soil, surface water and sediment, and its fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

2-nitropropane rapidly volatilizes from soil, and also has the potential to leach in moist soils.

2-nitropropane undergoes minimal degradation in soil (Freitag et al. 1988).

2-nitropropane is highly soluble in water (Baker and Bollmeier 1981). It is expected to have a short half-life in surface water because of its propensity for rapid volatilization, based on its high vapor pressure (Dougan et al. 1976). Adsorption of 2-nitropropane to suspended solids or sediment is not expected, based on its low  $K_{oc}$  value (Lyman 1982).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

2-nitropropane does not bioconcentrate in aquatic organisms (Baker and Bollmeier 1981; Freitag et al. 1988). 2-nitropropane is readily absorbed by the gastrointestinal tract and the lungs, when inhaled. Accumulation of 2-nitropropane in tissues of mammals is low because it is rapidly metabolized and eliminated after uptake (Nolan et al. 1982). 2-nitropropane may be excreted unchanged in expired air or as nitrite and nitrate in the urine (Browning 1965).

No information was available on the fate of 2-nitropropane in birds or plants.

## **POLYNUCLEAR AROMATIC HYDROCARBONS (PAHS)**

### **1.0 SUMMARY**

Polynuclear aromatic hydrocarbons (PAH) are a class of semi-volatile compounds that have a high affinity for soil and sediment particles. PAHs have low water solubility. Low molecular weight PAHs volatilize and photolyze from soil and surface water, and may be biodegraded as well. High molecular weight PAHs are resistant to volatilization, photolysis, and biodegradation. PAHs can be bioconcentrated to high concentrations by some aquatic organisms. However, many aquatic organisms can metabolize PAHs. The main PAH exposure route for upper-trophic-level receptors is ingestion. However, wildlife can readily metabolize PAHs and eliminate the by-products. Therefore, food chain transfer and biomagnification are anticipated to be minimal.

The following is a profile of the fate of PAHs in soil, surface water and sediment; and the fate after uptake by ecological receptors. The PAHs considered are benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

PAHs strongly adsorb to the soil; therefore, leaching to groundwater and volatilization are slow insignificant processes in most instances (HSDB 1997). However, the persistence of PAHs in soil is dependent upon the number of condensed rings that a PAH contains. The major source of degradation of PAHs in soil is microbial metabolism (ATSDR 1995). Volatilization and photolysis were determined to be important processes for the degradation of PAHs containing less than four aromatic rings, when analyzed from four surface soils amended with PAHs in sewage sludge. However, PAHs containing four or more aromatic rings showed insignificant abiotic losses (Wild and Jones 1993).

Within aquatic systems, PAHs are found sorbed to particles suspended in the water column or particles which have settled to the bottom. This is due to the low solubility and high affinity PAHs have for organic carbon. Studies have estimated that two-thirds of PAHs found in aquatic systems are in particle form and

only one-third are in dissolved form (Eisler 1987). Low molecular weight PAHs (2 to 3 rings) studied in estuaries show that the primary removal processes are volatilization and biodegradation, while high molecular weight PAHs (4 or more rings) volatilize and adsorb to suspended sediments (Thomas 1982; Southworth et al. 1978; Southworth 1979).

Photo-oxidation, chemical oxidation, and biodegradation by aquatic microorganisms are the primary degradation processes associated with PAHs in water (Neff 1979). The process of photo-oxidation varies widely among PAHs when considering the rate and extent of degradation. Benzo(a)pyrene is the most resistant to photo-oxidation, while benzo(a)anthracene is the most sensitive (Neff 1979). Microbial degradation of PAHs in water is very rapid under oxygenated conditions, but extremely slow under anoxic conditions (Neff 1979).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Sources of PAH accumulation in aquatic organisms include water, sediment, and food. Bioconcentration factors can range from low to very high, depending on the PAH and the receptor. Invertebrates and bottom-dwelling fish may accumulate PAHs through ingestion of sediment (Eisler 1987).

Studies indicate that fish are capable of metabolizing PAHs by the mixed function oxidase (MFO) system in the liver. The breakdown products are then eliminated through the urine and feces. Half-lives ranging from 2 to 9 days have been reported for the elimination of PAHs in fish (Niimi 1987). Chrysene has a near-surface half-life computed for sunlight at latitude 40°N of 4.4 hours (Zepp and Schlotzhauer 1979). Assimilation of PAHs from contaminated food is readily achieved by fish and crustaceans; however, this process is limited for mollusks and polychaete worms (Eisler 1987). It is also noted that aquatic organisms such as phytoplankton, certain zooplankton, mussels, scallops, and snails lack a metabolic detoxification enzyme system. Therefore, these organisms have potential for PAH accumulation (Malins 1977).

PAHs can be introduced into mammals through ingestion, inhalation, and dermal exposure. Because PAHs are highly lipid soluble and can cross epithelial membranes, they are readily absorbed from the gastrointestinal tract and lung (HSDB 1997). PAHs are absorbed through the mucous lining of bronchi when inhaled (Bevan and Ulman 1991) and taken up by the gastrointestinal tract in fat-soluble compounds when ingested. Passive diffusion is the process in which PAHs are distributed following percutaneous

absorption (Ng et al. 1991). Once absorbed into the body, PAHs are distributed to the lymph fluid and then the blood stream. Following oral or inhalation exposure, PAHs are widely distributed in animal tissue (Bartosek et al. 1984; Withey et al. 1991; Yamazaki and Kakiuchi 1989).

PAHs have limited transfer across the placenta; therefore, PAH levels are generally lower in the fetus, when compared to maternal levels (Neubert and Tapken 1988; Withey et al. 1992). The major metabolism sites for PAHs are the liver and kidneys. Additional sites of metabolism include the adrenal glands, testes, thyroid, lungs, skin, sebaceous glands, and placenta (Meditext 1997). PAHs are primarily excreted through the urine and bile (Bevan and Weyand 1988; Grimmer et al. 1988; Petridou-Fischer et al. 1988; Weyand and Bevan 1986; Wolff et al. 1989).

PAHs may be taken up by terrestrial plants from the soil or air depending on the concentration, solubility, and molecular weight of the PAHs. Lower molecular weight PAHs are absorbed by plants more readily than higher molecular weight PAHs (USFWS 1987). Some plants are capable of producing benzo(b)fluoranthene (HSDB 1997). The partitioning of PAHs between vegetation and the atmosphere was found to be primarily dependent upon the atmospheric gas-phase PAH concentration and the ambient temperature, when studied throughout the growing season under natural conditions (Simonich and Hites 1994). Above-ground parts of vegetables have been found to contain more PAHs than underground parts, mainly attributable to airborne deposition and subsequent adsorption (USFWS 1987). Growth promoting effects were observed in higher plants, as well as cultures of lower plants, when benzo(a)anthracene, indeno(1,2,3-cd)pyrene, and benzo(b)fluoranthene were tested in a series of soil and hydrocultures (Graf and Nowak 1968).

Information was not available on the fate of PAHs in exposed birds.

## **POLYCHLORINATED BIPHENYLS (PCBs)**

### **1.0 SUMMARY**

Polychlorinated biphenyls (PCB) are mixtures of different congeners of chlorobiphenyl. PCBs are a group of highly fat-soluble, semi-volatile compounds that readily bioaccumulate and biomagnify in ecological receptors, especially upper-trophic-level carnivores in aquatic food webs. In general, PCBs adsorb strongly to soil and sediment, and are soluble in fatty tissues. Volatilization and biodegradation of the lower chlorinated congeners also occur. The toxicological properties of individual PCBs are influenced primarily by: (1) lipophilicity, which is correlated with  $\log K_{ow}$ , and (2) steric factors resulting from different patterns of chlorine substitution on the biphenyl molecule. In general, PCB isomers with high  $K_{ow}$  values and high numbers of substituted chlorines in adjacent positions constitute the greatest environmental concern. Biological responses to individual isomers or mixtures vary widely, even among closely related taxonomic species.

The following is a profile of the fate of PCBs in soil, surface water, and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water, and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

The environmental fate of PCBs in soil depends on the degree of chlorination of the molecule. In general, adsorption and the persistence of PCBs increases with an increase in the degree of chlorination (EPA 1988). Mono-, di-, and trichlorinated biphenyls (Aroclors 1221 and 1232) biodegrade relatively rapidly. Tetrachlorinated biphenyls (Aroclors 1016 and 1242) biodegrade slowly, and higher chlorinated biphenyls (Aroclors 1248, 1254, and 1260) are resistant to biodegradation (HSDB 1997). Although biodegradation of higher chlorinated congeners may occur very slowly, no other degradation mechanisms have been shown to be significant in soil (HSDB 1997). Vapor loss of PCBs from soil surfaces appears to be an important mechanism with the rate of volatilization decreasing with increasing chlorination. Although the volatilization rate may be low, the total loss by volatilization over time may be significant because of persistence and stability of PCBs (Sklarew and Girvin 1987).

In water, adsorption to sediments and organic matter is a major fate process for PCBs (EPA 1988; Callahan et al. 1979). Volatilization of dissolved PCBs is an important aquatic process. Strong PCB adsorption to sediment significantly decreases the rate of volatilization, with higher chlorinated PCBs having longer half-lives than the lower chlorinated PCBs (EPA 1988).

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Diet is a major route of PCB uptake in many aquatic species (Eisler 1986). However, some species accumulate PCBs from the water column to a much larger extent than the diet, even when comparing closely-related species. Based on its high log  $K_{ow}$  value, receptors are expected to bioconcentrate and bioaccumulate PCBs to tissue levels much greater than the concentrations in water and sediment (Eisler 1986). Due to their high lipophilicity, PCBs concentrate mostly in fatty tissues. For upper-trophic-level receptors, diet is the main exposure pathway for PCB exposure (Eisler 1986). In aquatic food webs, evidence indicates that PCBs biomagnify in upper trophic levels, but not in lower trophic levels (Shaw and Connell 1982).

Among mammals, aquatic predators (e.g., mink, otters, seals, etc.) have been found to accumulate PCBs to significant levels. Lower chlorinated PCBs are eliminated more rapidly from lipids than higher chlorinated PCBs. Placental transfer of PCBs occurs in mammals (Hidaka et al. 1983).

The primary biochemical effect of PCBs is to induce hepatic mixed function oxidase systems, increasing an organism's capacity to biotransform or detoxify xenobiotic chemicals. PCBs also induce hepatic enzymes that metabolize naturally occurring steroidal hormones (Peakall 1975). These hepatic microsomal enzyme systems are most likely correlated with observed adverse reproductive effects (Tanabe 1988).

PCBs accumulate in bird tissues and eggs (Eisler 1986). Residues of PCBs in birds are affected by numerous biotic factors including fat content, tissue specificity, sex, and the developmental stage of an organism (Eisler 1986). Sexual differences in PCB bioaccumulation are pronounced due to the female's ability to pass a significant portion of the PCB burden to eggs (Lemmetyinen and Rantamaki 1980).

Water snakes (*Nerodia spp.*) and turtles accumulate PCB levels similar to those of PCB residues in their prey. Aroclor 1260 accounted for most of the PCBs detected in water snakes (Sabourin et al. 1984;

Olafsson et al. 1983). These data suggest diet is an important route of PCB transfer in reptiles (McKim and Johnson 1983).

Organic matter and clay content of soil influences the bioavailability of PCBs to plants (Strek and Weber 1982). Uptake of PCBs from soils by plants has been documented, however, only very low amounts are typically accumulated (Iwata et al 1974, Iwata and Gunther 1976, Weber and Mrozek 1979). Effects of PCBs on plants include reduced growth and chlorophyll content, and negative effects on photosynthesis (Strek and Weber 1982).

Terrestrial and aquatic plants bioconcentrate PCBs (Sawhney and Hankin 1984). Aquatic plants also bioaccumulate PCBs from both the water column and sediments. Transfer of PCBs on microparticulate materials to phytoplankton is well documented, as is partitioning from aqueous solution into algal lipids (Rohrer et al. 1982).

## **PENTACHLOROPHENOL**

### **1.0 SUMMARY**

Pentachlorophenol (PCP) has a strong affinity for soil, with sorption higher at lower pH and with increased organic content. Microorganisms readily metabolize PCP in soil, surface water, and sediment. Photolysis rapidly breaks down PCP in surface water. Ecological receptors will rapidly absorb PCP, but will also rapidly excrete it. Therefore, the potential for bioconcentration and bioaccumulation is only moderate. PCP biomagnification has not been observed.

The following is a profile of the fate of PCP in soil, surface water, and sediment, and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

PCP adsorbs strongly to soil, with adsorption higher in acidic conditions (Callahan et al. 1979). The amount of PCP adsorbed to soil at a given pH also increases with increasing organic content of the soil (Chang and Choi 1974). The half-life of PCP in soil ranges from weeks to months (Ide et al. 1972; Murthy 1979; Rao and Davidson 1982). Photolysis and hydrolysis do not appear to be significant processes of degradation in soil (Ball 1987). In certain soil environments, PCP may volatilize; however, in general, mobility of PCP in soil is limited (Arsenault 1976).

Biodegradation is considered the major transformation mechanism for PCP in soil, with PCP metabolized rapidly by acclimated microorganisms (Kaufman 1978). The main degradation products of PCP in soil are 2,3,7,8-tetrachlorophenol and carbon dioxide (Knowlton and Huckins 1983).

The fate of PCP in water and sediment is heavily dependent upon the pH of the water. At lower pH, more of the PCP dissociates and is available for degradation (Weiss et al. 1982). PCP also adsorbs to sediment more readily under acidic conditions, and is more mobile under neutral or alkaline conditions (Kuwatsuka and Igarashi 1975).

In surface water, photolysis and biodegradation are the predominant transformation processes for PCP (ATSDR 1994). Photolysis occurs mainly at the water surface, with its impact decreasing with increasing depth (Callahan et al. 1979). The reported half-life for the photolysis of PCP is about 1 hour (Callahan et al. 1979). Biodegradation of PCP can occur under both aerobic and anaerobic conditions, with more rapid degradation under aerobic conditions (Pignatello et al. 1983). The greatest biodegradation of PCP was observed in the top 0.5 to 1 cm layer of sediment.

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

The aquatic toxicity of PCP depends on water pH; at low pH, PCP is more lipophilic, with a high potential for accumulation. At alkaline pH, PCP is more hydrophilic, with a decreased potential for bioconcentration (Eisler 1989). Fish and bivalves may moderately bioconcentrate PCP (Makela et al. 1991).

Accumulation of PCP in fish is rapid, and occurs primarily by direct uptake from water rather than through the food chain or diet. In fish, PCP residues are found in the liver, gill, muscle, and hepatopancreas. PCP is readily metabolized in the liver and hepatopancreas. (Menzie 1978). Half-lives in tissues are less than 24 hours (Eisler 1989).

In mammals, PCP may be absorbed into the body through inhalation, diet or skin contact (Eisler 1989). The degree of accumulation is small, since PCP is efficiently and rapidly excreted. The highest residuals are found in the liver and kidneys, likely reflecting that these organs are the principal organs for metabolism and excretion (Gasiewicz 1991). Small amounts of PCP have been shown to cross the placenta (Shepard 1986).

Uptake into rice has been demonstrated in a 2-year study under flooded conditions. After a single application of radiolabeled PCP, 12.9% of the application was taken up by the plants within the first year, with the highest levels found in the roots (Eisler 1989).

## **THALLIUM**

### **1.0 SUMMARY**

In the environment, thallium exists in either the monovalent (thallous) or trivalent (thallic) form. Thallium is chemically reactive with air and moisture, undergoing oxidation. Thallium is relatively insoluble in water, although thallium compounds exhibit a wide range of solubilities. Thallium adsorbs to soil and sediment and is not transformed or biodegraded. In aquatic organisms, thallium is absorbed primarily from ingestion and thereafter bioconcentrates in the organism. In mammals, thallium is absorbed primarily from ingestion and is distributed to several organs and tissues, with the highest levels reported in the kidneys. Thallium exposure in mammals causes cardiac, neurologic, reproductive and dermatological effects. Thallium is taken up by plants and inhibits chlorophyll formation and seed germination.

The following is a profile of the fate of thallium in soil, surface water and sediment; and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

In soil, thallium exists in either the monovalent (thallous) or trivalent (thallic) form, with the monovalent form being more common and stable and, therefore, forming more numerous salts (Hampel 1968). Thallium is reactive with air and moisture, oxidizing slowly in air at 20°C and more rapidly with increasing temperatures (Standen 1967). Moisture increases the oxidation of thallium. Thallium adsorbs to soil and is not transformed or biodegraded (Callahan et al. 1979).

Elemental thallium is relatively insoluble in water (Windholz 1976). However, thallium compounds exhibit solubilities ranging from 220 mg/L to more than 700,000 mg/L (Standen 1967; Weast 1975).

Thallium adsorbs to sediments and micaceous clays (Callahan et al. 1979; Frantz and Carlson 1987). Data regarding the transformation or biodegradation of thallium in water were not located.

### **3.0 ECOLOGICAL RECEPTORS**

The primary exposure route for aquatic organisms exposed to thallium is ingestion. Thallium bioconcentrates in aquatic organisms (Zitko and Carson 1975). Toxic effects have been observed in numerous aquatic organisms including daphnia, fat-head minnow, sheepshead minnow, saltwater shrimp, atlantic salmon, bluegill sunfish, and others (USEPA 1980).

Birds and mammals are exposed to thallium via ingestion of soil, water, and plant material (Lie et al. 1960). Following absorption, thallium is distributed to numerous organs including the skin, liver, and muscle, with the greatest amount found in the kidneys (Downs et al. 1960; Manzo et al. 1983). Thallium is excreted primarily in the urine, with some excretion in the feces (Lehman and Favari 1985). Thallium is distributed from the maternal circulation to the fetus (Gibson et al. 1967; Gibson and Becker 1970). Various effects and toxic responses have been reported. Tikhonova (1967) reported paralysis and pathological changes in the liver, kidneys, and stomach mucosa in rabbits chronically exposed to thallium. Formigli et al. (1986) reported testicular toxicity in rats exposed to thallium. Grunfeld et al. (1963) reported changes in the electrocardiographs of rabbits following oral exposure to thallium.

Some levels of thallium occurs naturally in plants (Seiler 1988). Thallium is taken up by the roots of higher plants (Cataldo and Wildung 1983). Thallium has been shown to inhibit chlorophyll formation and seed generation (OHM/TADS 1997).

## **VINYL CHLORIDE**

### **1.0 SUMMARY**

Vinyl chloride is a low molecular weight organic compound that rapidly volatilizes after released to soil and surface water. Aquatic organisms may take up vinyl chloride, however it is rapidly depurated because it is highly water-soluble. Routes of exposure for wildlife include inhalation, ingestion, and dermal exposure. Bioaccumulation in terrestrial and aquatic organisms is not an important process in the environmental fate of vinyl chloride because of its high volatility and the rapid metabolism by higher-trophic-level receptors.

The following is a profile of the fate of vinyl chloride in soil, surface water and sediment, and the fate after uptake by ecological receptors. Section 2 discusses the environmental fate and transport in soil, surface water, and sediment. Section 3 discusses the fate in ecological receptors.

### **2.0 FATE IN SOIL, SURFACE WATER, AND SEDIMENT**

Vinyl chloride in dry soil has a very short half-life (less than 1 day) (Jury et al. 1984). Vinyl chloride has a high vapor pressure, indicating rapid volatilization from dry soil surfaces (Riddick et al. 1986; Verschueren 1983). Vinyl chloride is also biodegraded and photolyzed in surface soil (ATSDR 1995; Nelson and Jewell 1993). Vinyl chloride does not adsorb to soil in significant amounts.

Vinyl chloride in surface water has a half-life of a few hours (Thomas 1982). An estimated half-life in fresh water for vinyl chloride of 2.5 hours was reported (Mabey et al. 1981). Vinyl chloride is slightly soluble (Cowfer and Magistro 1983). However, vinyl chloride released to surface water will quickly volatilize, negating other fate processes that might be significant based on physical and chemical parameters.

### **3.0 FATE IN ECOLOGICAL RECEPTORS**

Vinyl chloride is not expected to significantly bioconcentrate in aquatic organisms because it has a very low log  $K_{ow}$  value. Bioconcentration and accumulation in aquatic carnivores is not expected because of the

high volatility of vinyl chloride and the rapid metabolism of vinyl chloride by higher-trophic-level organisms (Freitag et al. 1985; Lu et al. 1977).

In mammals, vinyl chloride may be absorbed by the body via inhalation (Bolt et al. 1977; Krajewski et al. 1980; Withey 1976), ingestion (Feron et al. 1981; Watanabe et al. 1976; Withey 1976) and dermal contact (Hefner et al. 1975). It is rapidly absorbed and distributed throughout the tissues following uptake. Because of the rapid metabolism and excretion of vinyl chloride, storage within the body is limited.

Information was not available on the fate of vinyl chloride in birds or plants.
