| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 96.95                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 150.6                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 7.88E-01<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.0E+03                         |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.55E-02                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.53E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.09E-05                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.32E+02                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.50E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 6.50E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 4.88E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 2.60E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| Vp (atm)                            | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.30E-01<br>at 25°C (liquid) |
| S (mg/L)                            | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.94E+03                     |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S, and Vp values that are provided in this table.                                                                                                                                                                                                                                                                            | 4.51E-03                     |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.36E-02                     |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.13E-05                     |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 9.60E+01                     |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 4.98E+01                     |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 4.98E-01                     |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.73+00                      |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.99E+00                     |
| $ksg$ (year) <sup>-1</sup>          | $Ksg$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                     |
| Fv (unitless)                       | Fv value was calculated by using the equation cited in Junge (1977). Recommended value of Fv was calculated by using the Vp value that is provided in the table.                                                                                                                                                                                                                                                                                                                                                | 1.00                         |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 96.95                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 223.7                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 4.63E-01<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 6.03E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 7.44E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                           | 8.16E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                           | 9.75E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 9.60E+01                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.80E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.80E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.85E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.52E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| H (atm·m <sup>3</sup> /mol)          | H value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S, and V <sub>p</sub> values that are provided in this table.                                                                                                                                                                                                                                                                                                     | 2.38E-07                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |      |    |      |    |      |    |      |    |      |
| D <sub>a</sub> (cm <sup>2</sup> /s)  | D <sub>a</sub> value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 2.69E-02                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |      |    |      |    |      |    |      |    |      |

| Kd <sub>s</sub> (cm <sup>3</sup> /g) | Kd <sub>s</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate Kd <sub>s</sub> , because the value varies, depending on the fraction of organic carbon in soil. Recommended Kd <sub>s</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table.                                               | 1.40E+00                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |      |    |      |    |      |    |      |    |      |
| Kd <sub>sw</sub> (L/Kg)              | Kd <sub>sw</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate Kd <sub>sw</sub> , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended Kd <sub>sw</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table. | 1.05E+01                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |      |    |      |    |      |    |      |    |      |

| $Kd_{bs}$ (cm <sup>3</sup> /g)                  | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 5.58E+00 |
| $ksg$ (year) <sup>-1</sup>                      | $ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                             | 3.61E+00 |
| $Fv$ (unitless)                                 | $Fv$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $Fv$ was calculated by using $T_m$ and $Vp$ values that are provided in this table. $Vp$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                            | 1.0      |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neill, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 112.99                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 172.7                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 6.66E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.68E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.81E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.21E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.71E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.78E+02                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.70E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 4.70E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.53E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 1.88E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.96E-01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

TABLE A-2-81

## CHEMICAL-SPECIFIC INPUTS FOR (CIS)-1,3-DICHLOROPROPENE (542-75-6)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 110.98                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 189.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.11E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.55E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.94E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.26E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.00E-05                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 5.60E+01                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.70E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.70E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.03E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.08E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 2.24E+01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

Note:

NA = Not applicable

ND = No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

TABLE A-2-82

## CHEMICAL-SPECIFIC INPUTS FOR DICHLORVOS (62-73-7)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value                        |

| $V_p$ (atm)                         | $V_p$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 6.93E-05<br>at 25°C (liquid) |
| $S$ (mg/L)                          | $S$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.6E+04                      |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 9.57E-07                     |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.32E-02                     |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.33E-06                     |
| $K_{ow}$ (unitless)                 | Recommended $K_{ow}$ value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.69E+01                     |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 1.85E+01                     |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.85E-01                     |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.38E+00                     |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 7.38E-01                     |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                          | 1.49E+01                     |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.00                         |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 380.93                         |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 449.1                          |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.31E-09<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.87E-01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.66E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.36E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 4.29E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.86E+05                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.55E+04                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.55E+02                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.91E+03                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.02E+03                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991)                                                                                                                                                                                                                                                                                                                                                                     | 2.34E+00                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 0.9860                         |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 222.24                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 232.6                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.17E-06<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 8.80E+02                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 5.48E-07                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.56E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.35E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.73E+04                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.20E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 8.20E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 6.15E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 3.28E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 4.52E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <i>V<sub>p</sub></i> (atm)                  | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 2.17E-06<br>at 25°C (liquid) |
| <i>S</i> (mg/L)                             | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 4.19E+03                     |
| <i>H</i> (atm·m <sup>3</sup> /mol)          | <i>H</i> value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the <i>MW</i> , <i>S</i> , and <i>V<sub>p</sub></i> values that are provided in this table.                                                                                                                                                                                                                                                                                                      | 1.01E-07                     |
| <i>D<sub>a</sub></i> (cm <sup>2</sup> /s)   | <i>D<sub>a</sub></i> value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.96E-02                     |
| <i>D<sub>w</sub></i> (cm <sup>2</sup> /s)   | <i>D<sub>w</sub></i> value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 7.13E-06                     |
| <i>K<sub>ow</sub></i> (unitless)            | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 4.30E+01                     |
| <i>K<sub>oc</sub></i> (mL/g)                | <i>K<sub>oc</sub></i> value was calculated by using the correlation equation with <i>K<sub>ow</sub></i> for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). <i>K<sub>oc</sub></i> value was calculated by using the recommended <i>K<sub>ow</sub></i> value that is provided in this table.                                                                                                                                                                                                             | 3.09E+01                     |
| <i>Kd<sub>s</sub></i> (cm <sup>3</sup> /g)  | <i>Kd<sub>s</sub></i> value was calculated by using the correlation equation with <i>K<sub>oc</sub></i> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate <i>Kd<sub>s</sub></i> , because the value varies, depending on the fraction of organic carbon in soil. Recommended <i>Kd<sub>s</sub></i> value was calculated by using the <i>K<sub>oc</sub></i> value that is provided in this table.                                               | 3.09E-01                     |
| <i>Kd<sub>sw</sub></i> (L/Kg)               | <i>Kd<sub>sw</sub></i> value was calculated by using the correlation equation with <i>K<sub>oc</sub></i> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate <i>Kd<sub>sw</sub></i> , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended <i>Kd<sub>sw</sub></i> value was calculated by using the <i>K<sub>oc</sub></i> value that is provided in this table. | 2.00E+01                     |
| <i>Kd<sub>bs</sub></i> (cm <sup>3</sup> /g) | <i>Kd<sub>bs</sub></i> value was calculated by using the correlation equation with <i>K<sub>oc</sub></i> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate <i>Kd<sub>bs</sub></i> , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended <i>Kd<sub>bs</sub></i> value was calculated by using the <i>K<sub>oc</sub></i> value that is provided in this table.           | 1.06E+01                     |
| <i>ksg</i> (year) <sup>-1</sup>             | <i>Ksg</i> value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                                                                                   | 3.61E+01                     |
| <i>Fv</i> (unitless)                        | <i>Fv</i> value was calculated by using the equation cited in Junge (1977). Recommended value of <i>Fv</i> was calculated by using the <i>V<sub>p</sub></i> value that is provided in the table.                                                                                                                                                                                                                                                                                                                                                                                 | 1.00                         |

| H (atm·m <sup>3</sup> /mol)          | H value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S, and V <sub>p</sub> values that are provided in this table.                                                                                                                                                                                                                                                                                                     | 3.24E-06                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |                 |   |       |   |       |   |       |   |       |   |       |   |        |   |       |   |        |   |        |    |       |    |       |    |      |    |      |    |      |
| D <sub>a</sub> (cm <sup>2</sup> /s)  | D <sub>a</sub> value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 5.84E-02                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |                 |   |       |   |       |   |       |   |       |   |       |   |        |   |       |   |        |   |        |    |       |    |       |    |      |    |      |    |      |

| Kd <sub>s</sub> (cm <sup>3</sup> /g) | Kd <sub>s</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate Kd <sub>s</sub> , because the value varies, depending on the fraction of organic carbon in soil. Recommended Kd <sub>s</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table.                                               | 1.26E+00                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |                 |   |       |   |       |   |       |   |       |   |       |   |        |   |       |   |        |   |        |    |       |    |       |    |      |    |      |    |      |
| Kd <sub>sw</sub> (L/Kg)              | Kd <sub>sw</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate Kd <sub>sw</sub> , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended Kd <sub>sw</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table. | 9.44E+00                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |                 |   |       |   |       |   |       |   |       |   |       |   |        |   |       |   |        |   |        |    |       |    |       |    |      |    |      |    |      |

| $Kd_{bs}$ (cm <sup>3</sup> /g)                  | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 5.04E+00 |
| $ksg$ (year) <sup>-1</sup>                      | $Ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                             | 3.61E+01 |
| $Fv$ (unitless)                                 | $Fv$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $Fv$ was calculated by using $T_m$ and $Vp$ values that are provided in this table. $Vp$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                            | 1.0      |

## CHEMICAL-SPECIFIC INPUTS FOR 3,3'-DIMETHYOXYBENZIDINE (119-90-4)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value                          |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 244.28                         |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 410.1                          |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 3.30E-10<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 2.40E+02                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 3.36E-10                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                           | 2.38E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                           | 5.60E-06                       |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 6.46E+01                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 3.65E+01                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.65E-01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.74E+00                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.46E+00                       |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                       | 1.41E+00                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 0.877                          |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                               |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 168.11                        |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 363                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994f).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.0E-07<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994f).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 5.4E+02                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                     | 1.25E-07                      |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database, U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                              | 3.18E-02                      |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database, U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                              | 9.15E-06                      |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994f).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.10E+01                      |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                    | 2.06E+01                      |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.06E-01                      |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.55E+00                      |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 8.25E-01                      |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                       | 1.41E+00                      |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.0                           |

Note:

NA= Not applicable

ND= No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

| H (atm·m <sup>3</sup> /mol)           | H value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S, and V <sub>p</sub> values that are provided in this table.                                                                                                                                                                                                                                                                                                                     | 4.82E-09                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                 |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |    |      |    |      |
| D <sub>a</sub> (cm <sup>2</sup> /s)   | D <sub>a</sub> value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 2.73E-02                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                 |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |    |      |    |      |

## CHEMICAL-SPECIFIC INPUTS FOR 2,4-DINITROPHENOL (51-28-5)

(Page 2 of 1)

| Parameter                     | Reference and Explanation                                                                                                                                                                                                                                                                                              | Value    |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| $k_{sg}$ (year) <sup>-1</sup> | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                           | 9.62E-01 |
| $F_v$ (unitless)              | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations. | 0.999    |

| MW (g/mole)                         | Howard (1989-1993)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 182.14                         |
| $T_m$ (K)                           | Howard (1989-1993)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 344                            |
| Vp (atm)                            | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.29E-07<br>at 25°C<br>(solid) |
| S (mg/L)                            | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.85E+02                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S and Vp values that are provided in this table.                                                                                                                                                                                                                                                                             | 1.46E-07                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.09E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.86E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 9.90E+01                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                    | 5.10E+01                       |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 5.10E-01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.83E+00                       |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 2.04E+00                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                       |
| Fv (unitless)                       | Fv value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of Fv was calculated by using S, $T_m$ , and Vp values that are provided in this table. Vp value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                         | 0.999                          |

| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 7.47E-07<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.05E+03                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                     | 1.30E-07                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.11E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.76E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 7.70E+01                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                    | 4.19E+01                       |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 4.19E-01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.14E+00                       |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.68E+00                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.0                            |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 88.10                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 284.9                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 5.00E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 9.00E+05                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 4.89E-06                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.20E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.05E-05                        |
| $K_{ow}$ (unitless)                 | $K_{ow}$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 5.40E-01                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 8.76E-01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 8.76E-03                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 6.57E-02                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 3.50E-02                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 184.24                         |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 401.1                          |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 4.74E-08<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 6.80E+01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.28E-07                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.95E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.24E-06                       |
| $K_{ow}$ (unitless)                 | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 8.71E+02                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 2.78E+02                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.78E+00                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.09E+01                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.11E+01                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 0.999                          |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 274.38                         |
| $T_m$ (K)                           | $T_m$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 248                            |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 3.7E-07<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.6E+01                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 4.12E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.50E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 5.21E-06                       |
| $K_{ow}$ (unitless)                 | Recommended $K_{ow}$ value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 9.55E+03                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 1.80E+03                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.80E+01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.35E+02                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 7.20E+01                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.20E+01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 0.998                          |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 343.1                          |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.31E-08<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 2.31E-01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.31E-05                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.59E-03                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 5.76E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.02E+03                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.04E+03                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.04E+01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.53E+02                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 8.16E+01                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 2.78E+01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 0.9839                         |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 380.93                         |
| $T_m$ (K)                           | U.S.EPA (1992a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 473.1                          |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1992a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 7.68E-10<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1992a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 2.46E-01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.19E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.07E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 5.76E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 7.79E+04                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.08E+04                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.08E+02                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.11E+02                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 4.32E+02                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991)                                                                                                                                                                                                                                                                                                                                                                     | 3.61E+04                       |
| $F_v$ (unitless)                    | --                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | ND                             |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 92.53                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 247.5                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 2.20E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 6.60E+04                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 3.08E-05                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.13E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.10E-05                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1.78E+00                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 2.22E+00                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.22E-02                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.66E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 8.88E-02                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                     |
| $MW$ (g/mole)                       | $MW$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 114.14              |
| $T_m$ (K)                           | --                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | NA                  |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 2.30E-02<br>at 25°C |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.90E+04            |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.38E-04            |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 8.07E-02            |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 9.35E-06            |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 3.89E+01            |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 2.46E+01            |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.46E-01            |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.85E+00            |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 9.80E-01            |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                 |
| $F_v$ (unitless)                    | $F_v$ value cited in NC DEHNR (1997).                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 1.0                 |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                          |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 124.15                   |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 373.0                    |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 3.50E-04 at 25°C (solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 4.90E+05                 |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 8.87E-08                 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 7.63E-02                 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 8.84E-06                 |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1.12E+00                 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 1.55E+00                 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table for a pH of 7.0.                                     | 1.55E-02                 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.16E-01                 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                     | 6.19E-02                 |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 7.88E+01                 |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.0                      |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                              |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 106.16                       |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 178.1                        |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.26E-02<br>at 25°C (liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.73E+02                     |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 7.73E-03                     |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.65E-02                     |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.49E-06                     |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.33E+03                     |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.04E+02                     |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.04E+00                     |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.53E+01                     |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 8.16E+00                     |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991) and Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                       | 2.53E+01                     |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                          |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 187.88                          |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 282.1                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.00E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 4.20E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 4.47E-04                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.17E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.19E-05                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 5.62E+01                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 3.28E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.28E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.46E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.31E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 162.1                     |
| $V_p$ (atm)                         | Verschueren (1983)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 1.44E+00 at 25°C (liquid) |
| $S$ (mg/L)                          | $S$ value cited in NC DEHNR (1996).                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 3.80E+05                  |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.67E-04                  |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.71E-01                  |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.44E-05                  |
| $K_{ow}$ (unitless)                 | Howard (1989-1993)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 5.01E-01                  |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 8.26E-01                  |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 8.26E-03                  |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 6.19E-02                  |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                     | 3.30E-02                  |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 2.13E+01                  |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                       |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 218.1                        |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 8.49E-09<br>at 25°C (liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.96E-01                     |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 8.37E-06                     |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.32E-02                     |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.22E-06                     |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.60E+05                     |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.11E+05                     |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.11E+03                     |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.33E+03                     |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 4.44E+03                     |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.10E+01                     |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 0.9350                       |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 202.26                         |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 383.1                          |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.07E-08<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.32E-01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 9.33E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.75E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.18E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.21E+05                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.91E+04                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 4.91E+02                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.68E+03                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.96E+03                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 5.75E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 0.992                          |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 166.22                         |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 389.1                          |
| $Vp$ (atm)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 8.17E-07<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.86E+00                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $Vp$ values that are provided in this table.                                                                                                                                                                                                                                                                    | 7.30E-05                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 3.63E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 7.88E-06                       |
| $K_{ow}$ (unitless)                 | $K_{ow}$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 1.47E+04                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.71E+03                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 7.71E+01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 5.78E+02                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 3.08E+02                       |
| $ksg$ (year) <sup>-1</sup>          | $Ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                       | 4.22E+00                       |
| $Fv$ (unitless)                     | $Fv$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $Fv$ was calculated by using $T_m$ and $Vp$ values that are provided in this table. $Vp$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                      | 0.9999                         |

| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 5.10E+00<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 5.50E+05                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.78E-04                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 5.00E-01                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.74E-05                       |
| $K_{ow}$ (unitless)                 | $K_{ow}$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 2.20E+00                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 2.62E+00                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.62E-02                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.96E-01                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.05E-01                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991)                                                                                                                                                                                                                                                                                                                                                                     | 3.61E+01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.00                           |

| $MW$ (g/mole)                       | U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 46.03                        |
| $T_m$ (K)                           | U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 282.0                        |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 5.40E-02<br>at 25°C (liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 1.00E+06                     |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.49E-06                     |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.22E-01                     |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.71E-05                     |
| $K_{ow}$ (unitless)                 | $K_{ow}$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 2.90E-01                     |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 5.39E-01                     |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 5.39E-03                     |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 4.04E-02                     |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 2.16E-02                     |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 3.61E+01                     |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.00                         |

| $S$ (mg/L)                          | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 2.40E-06                 |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 7.50E-06                 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.11E-02                 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 3.89E-06                 |
| $K_{ow}$ (unitless)                 | U.S. EPA (1992d)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.58E+08                 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 9.77E+07                 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 9.77E+05                 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 7.33E+06                 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 3.91E+06                 |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 1.09E-01                 |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.62E-02                 |

| MW (g/mole)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 409.31                   |
| $T_m$ (K)                           | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 509.1                    |
| $V_p$ (atm)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.75E-13 at 25°C (solid) |
| S (mg/L)                            | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.35E-06                 |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 5.30E-05                 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated by using Equation A-3-2. Recommended value was calculated by using the MW and $D_a$ values that are provided in the tables in Appendix A-2 for 2,3,7,8-TCDF.                                                                                                                                                                                                                                                                                                                         | 1.55E-02                 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 3.99E-06                 |
| $K_{ow}$ (unitless)                 | U.S. EPA (1992d)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 8.32E+07                 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 5.13E+07                 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 5.13E+05                 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.85E+06                 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 2.05E+06                 |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 3.57E-01                 |
| Fv (unitless)                       | Fv value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of Fv was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                        | 3.47E-02                 |

| $V_p$ (atm)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.41E-13 at 25°C (solid) |
| $S$ (mg/L)                          | Homologue group average value obtained from U.S. EPA (1994a).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 1.40E-06                 |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 5.30E-05                 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated by using Equation A-3-2. Recommended value was calculated by using the $MW$ and $D_a$ values that are provided in the tables in Appendix A-2 for 2,3,7,8-TCDF.                                                                                                                                                                                                                                                                                                                       | 1.55E-02                 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 3.99E-06                 |
| $K_{ow}$ (unitless)                 | Homologue group average value obtained from U.S. EPA (1992d).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 8.32E+07                 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 5.13E+07                 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 5.13E+05                 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.85E+06                 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 2.05E+06                 |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value was calculated using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                       | 3.57E-01                 |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 2.01E-02                 |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 368.1                    |
| $Vp$ (atm)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.29E-07 at 25°C (solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.73E+01                 |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $Vp$ values that are provided in this table.                                                                                                                                                                                                                                                                    | 5.87E-06                 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.12E-02                 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 5.69E-06                 |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.04E+05                 |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.53E+03                 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                                 | 9.53E+01                 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 7.15E+02                 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 3.81E+02                 |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                          | 1.41E+00                 |
| $Fv$ (unitless)                     | $Fv$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $Fv$ was calculated by using $S$ , $T_m$ , and $Vp$ values that are provided in this table. $Vp$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                              | 1.0                      |

| $MW$ (g/mole)                       | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 389.32                         |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 430.1                          |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 5.71E-09<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 2.68E-01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 8.29E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.32E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.23E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 5.62E+04                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 7.18E+03                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 7.18E+01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 5.38E+02                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 2.87E+02                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 4.58E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 0.9948                         |

| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.20E-05                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.15E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.12E-06                       |
| $K_{ow}$ (unitless)                 | U.S. EPA (1992d)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 6.17E+07                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a; 1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                                         | 3.80E+07                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.80E+05                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.85E+06                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 1.52E+06                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 1.09E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 5.96E-02                       |

| $V_p$ (atm)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 4.74E-14 at 25°C (solid) |
| S (mg/L)                            | Homologue group average value obtained from U.S. EPA (1994a).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 4.40E-06                 |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.20E-05                 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated by using Equation A-3-2. Recommended value was calculated by using the MW and $D_a$ values that are provided in the tables in Appendix A-2 for 2,3,7,8-TCDD.                                                                                                                                                                                                                                                                                                                         | 1.15E-02                 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.12E-06                 |
| $K_{ow}$ (unitless)                 | Homologue group average value obtained from U.S. EPA (1992d).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 1.78E+07                 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 1.10E+07                 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.10E+05                 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.22E+05                 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 4.39E+05                 |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value assumed to be the same as the $ksg$ value calculated for 1,2,3,4,7,8-HexaCDD. $ksg$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                          | 1.09E-01                 |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 2.89E-02                 |

| MW (g/mole)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 390.87                   |
| $T_m$ (K)                           | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 516.1                    |
| $V_p$ (atm)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 6.45E-14 at 25°C (solid) |
| $S$ (mg/L)                          | Homologue group average value obtained from U.S. EPA (1994a).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 4.40E-06                 |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S.EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.20E-05                 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.15E-02                 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.12E-06                 |
| $K_{ow}$ (unitless)                 | Homologue group average value obtained from U.S. EPA (1994a).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 1.78E+07                 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a; 1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                                         | 1.10E+07                 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.10E+05                 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.22E+05                 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 4.39E+05                 |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value was assumed to be the same as the $ksg$ value for 1,2,3,4,7,8-HexaCDD. $ksg$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                 | 1.09E-01                 |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 1.53E-02                 |

| $T_m$ (K)                           | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 498.6                    |
| $V_p$ (atm)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 3.16E-13 at 25°C (solid) |
| S (mg/L)                            | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 8.25E-06                 |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.40E-05                 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated by using Equation A-3-2. Recommended value was calculated by using the MW and $D_a$ values that are provided in the tables in Appendix A-2 for 2,3,7,8-TCDF.                                                                                                                                                                                                                                                                                                                         | 1.62E-02                 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.23E-06                 |
| $K_{ow}$ (unitless)                 | Homologue group average value obtained from U.S. EPA (1992d)                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 1.78E+07                 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 1.10E+07                 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.10E+05                 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.22E+05                 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 4.39E+05                 |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                      |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 4.86E-02                 |

| $T_m$ (K)                           | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 505.1                    |
| $V_p$ (atm)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 2.89E-13 at 25°C (solid) |
| S (mg/L)                            | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.77E-05                 |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 6.10E-06                 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated by using Equation A-3-2. Recommended value was calculated by using the MW and $D_a$ values that are provided in the tables in Appendix A-2 for 2,3,7,8-TCDF.                                                                                                                                                                                                                                                                                                                         | 1.62E-02                 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.23E-06                 |
| $K_{ow}$ (unitless)                 | Homologue group average value obtained from U.S. EPA (1992d)                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 1.78E+07                 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 1.10E+07                 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.10E+05                 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.22E+05                 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 4.39E+05                 |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                      |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 5.15E-02                 |

| $S$ (mg/L)                          | Homologue group average value obtained from U.S. EPA (1994a).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 1.30E-05                       |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.00E-05                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated by using Equation A-3-2. Recommended value was calculated by using the $MW$ and $D_a$ values that are provided in the tables in Appendix A-2 for 2,3,7,8-TCDF.                                                                                                                                                                                                                                                                                                                       | 1.62E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.23E-06                       |
| $K_{ow}$ (unitless)                 | Homologue group average value obtained from U.S. EPA (1992d).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 1.78E+07                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 1.10E+07                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.10E+05                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.22E+05                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 4.39E+05                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                            |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 0.5759                         |

| $S$ (mg/L)                          | Homologue group average value obtained from U.S. EPA (1994a).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 1.30E-05                       |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.00E-05                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated by using Equation A-3-2. Recommended value was calculated by using the $MW$ and $D_a$ values that are provided in the tables in Appendix A-2 for 2,3,7,8-TCDF.                                                                                                                                                                                                                                                                                                                       | 1.62E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.23E-06                       |
| $K_{ow}$ (unitless)                 | Homologue group average value obtained from U.S. EPA (1992d).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 1.78E+07                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 1.10E+07                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.10E+05                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.22E+05                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 4.39E+05                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                            |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 5.47E-02                       |

| $MW$ (g/mole)                       | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 260.76                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 252.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.33E-04<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.54E+00                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.39E-02                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.73E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.33E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 5.38E+04                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 6.94E+03                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 6.94E+01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 5.20E+02                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 2.77E+02                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 284.8                          |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 504.1                          |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.62E-08<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 8.62E-03                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                     | 5.35E-04                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.41E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.84E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.18E+05                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.00E+04                       |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 8.00E+02                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 6.00E+03                       |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 3.20E+03                       |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                       | 1.21E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.0                            |

| $MW$ (g/mole)                       | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 272.77                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 264.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 9.63E-05<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.53E+00                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.72E-02                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.61E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.21E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 8.07E+04                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 9.51E+03                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 9.51E+01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 7.13E+2                         |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 3.80E+02                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 6.21E-04<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.08E+01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 3.60E-03                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.77E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.88E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 9.66E+03                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 1.82E+03                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.82E+01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.36E+01                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 7.27E+01                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.0                            |

| $T_m$ (K)                           | Budavari, O'Neil, Smith and Heckleman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 437.1                          |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 3.60E-15<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 3.0E-03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 4.88E-10                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 3.46E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.01E-06                       |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 3.47E+07                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 1.08E+06                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.08E+04                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.08E+04                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 4.31E+04                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 7.71E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.4E-04                        |

| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                          | 4.86E-09                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from WATER8 model database U.S. EPA (1995d)                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.90E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from WATER8 model database U.S. EPA (1995d)                                                                                                                                                                                                                                                                                                                                                                                                                                            | 5.66E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 8.22E+06                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                                                         | 4.11E+06                       |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 4.11E+04                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.08E+05                       |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.64E+05                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 3.47E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using S, $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                             | 0.007                          |

| $MW$ (g/mole)                       | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 138.21                       |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 265.1                        |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 5.38E-04<br>at 25°C (liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.20E+04                     |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.20E-06                     |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 5.22E-02                     |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.50E-06                     |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 5.00E+01                     |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 2.99E+01                     |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.99E-01                     |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.25E+00                     |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.20E+00                     |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                     |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.0                          |

## CHEMICAL-SPECIFIC INPUTS FOR LEAD (7439-92-1)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                                                                                                                                                                                                                 | Value    |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                           |          |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                             | 207.2    |
| $T_m$ (°K)                          | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                             | 600.5    |
| $V_p$ (atm)                         | All metals, except mercury, are assumed to be nonvolatile at ambient temperatures.                                                                                                                                                                                                                                                                        | 0.0      |
| $S$ (mg/L)                          | All metals, except mercury, are assumed to be insoluble in water.                                                                                                                                                                                                                                                                                         | 0.0      |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value is assumed to be zero, because the $V_p$ and $S$ values are zero for all metals, except mercury.                                                                                                                                                                                                                                                | 0.0      |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                  | 5.43E-02 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                  | 6.28E-06 |
| $K_{ow}$ (unitless)                 | --                                                                                                                                                                                                                                                                                                                                                        | NA       |
| $K_{oc}$ (mL/g)                     | --                                                                                                                                                                                                                                                                                                                                                        | NA       |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was obtained from Baes, Sharp, Sjoreen, and Shor (1984), which states that several factors, such as experimental methods and soil type, could influence partitioning or $Kd_s$ values. Baes, Sharp, Sjoreen, and Shor (1984) compares values between various literature sources and provide this value, which is based on its best judgment. | 9.00E+02 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f).                                                                                                                                                                                    | 9.00E+02 |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f).                                                                                                                                                                                    | 9.00E+02 |
| $k_{sg}$ (year) <sup>-1</sup>       | --                                                                                                                                                                                                                                                                                                                                                        | ND       |
| $F_v$ (unitless)                    | Because they are nonvolatile, metals are assumed to be 100 percent in particulate phase and zero percent in the vapor phase, as cited in U.S. EPA (1994f).                                                                                                                                                                                                | 0.0      |

Note:

NA = Not applicable

ND = No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

TABLE A-2-129

## CHEMICAL-SPECIFIC INPUTS FOR MALATHIONE (121-75-5)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value                           |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 330.36                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 276                             |
| $V_p$ (atm)                         | $V_p$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 1.04E-08<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.43E+02                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.40E-08                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.47E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 5.29E-06                        |
| $K_{ow}$ (unitless)                 | Recommended $K_{ow}$ value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.29E+02                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 9.81E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 9.81E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 7.36E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 3.92E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 3.61E+01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 0.946                           |

| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.39E-04                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 1.15E-01                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 1.33E-05                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995)                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 3.47E+00                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 3.74E+00                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.74E-02                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.80E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.49E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be zero due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 0.0                             |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 32.04                        |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 175.3                        |
| $V_p$ (atm)                         | $V_p$ value cited in Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.30E-01<br>at 25°C (liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 2.90E+04                     |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.44E-04                     |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 4.58E-01                     |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.64E-05                     |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995)                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 1.95E-01                     |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                  | 3.96E-01                     |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.96E-03                     |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.97E-02                     |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.58E-02                     |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 3.61E+01                     |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.00                         |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 345.65                         |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 351.1                          |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.62E-09<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 8.84E-02                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.33E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.30E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 5.59E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.36E+04                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.00E+04                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 8.00E+02                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 6.00E+03                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 3.20E+03                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 6.93E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 0.901                          |

| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 175.1                           |
| $V_p$ (atm)                         | $V_p$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 2.84E-01<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 2.44E+05                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 8.64E-05                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.23E-01                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.10E-05                        |
| $K_{ow}$ (unitless)                 | Recommended $K_{ow}$ value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.90E+00                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 3.25E+00                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.25E-02                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.44E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.30E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 0.0                             |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.00                            |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 94.95                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 179.44                          |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.16E+00<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.45E+04                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.41E-02                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.28E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.21E-05                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.30E+01                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.00E+00                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 9.00E-02                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 6.75E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 3.60E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 5.68E+00<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 6.34E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 4.52E-02                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.13E-01                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.39E-05                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 8.00E+00                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.00E+00                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 6.00E-02                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 4.50E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 2.40E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boehling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                     | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 187.1                     |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.20E-01 at 25°C (liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 2.40E+05                  |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 3.61E-05                  |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.35E-01                  |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.03E-05                  |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1.91E+00                  |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 2.34E+00                  |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                                 | 2.34E-02                  |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.76E-01                  |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 9.36E-02                  |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 3.61E+01                  |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                       |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 188.4                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 2.50E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 2.00E+04                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.25E-04                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.59E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.36E-06                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1.55E+01                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 1.20E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.20E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 9.00E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 4.80E-01                        |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                       | 3.61E+01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 310.1                          |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1992a).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.30E-08<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1992a).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 5.00E+01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.84E-08                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.87E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.43E-06                       |
| $K_{ow}$ (unitless)                 | $K_{ow}$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 7.20E+02                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 2.40E+02                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.40E+00                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.80E+01                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 9.59E+00                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 7.03E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 0.966                          |

| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 2.20E+00<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.45E+04                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.64E-02                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 6.10E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 7.06E-06                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 4.17E+01                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 2.60E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.60E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.95E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                     | 1.04E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 84.94                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 178.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.87E-01<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.74E+04                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.38E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.69E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.25E-05                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.80E+01                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.00E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.00E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 7.50E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 4.00E-01                        |
| $ksg$ (year) <sup>-1</sup>          | $Ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                       | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Budavari, O'Neill, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 128.16                         |
| $T_m$ (K)                           | Budavari, O'Neill, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 353.3                          |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.17E-04<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.11E+01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 4.82E-04                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 5.26E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d)                                                                                                                                                                                                                                                                                                                                                                                                                                                | 8.92E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.36E+03                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.19E+03                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.19E+01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.93E+01                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 4.76E+01                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 5.27E+00                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.0                            |

| Parameter                           | Reference and Explanation                                                                                                                                              | Value                                              |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <b>Chemical/Physical Properties</b> |                                                                                                                                                                        |                                                    |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                          | 58.69                                              |
| $T_m$ (°K)                          | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                          | 1,828                                              |
| $V_p$ (atm)                         | All metals, except mercury, are assumed to be nonvolatile at ambient temperatures.                                                                                     | 0.0                                                |
| $S$ (mg/L)                          | All metals, except mercury, are assumed to be insoluble in water.                                                                                                      | 0.0                                                |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value is assumed to be zero, because the $V_p$ and $S$ values are zero for all metals, except mercury.                                                             | 0.0                                                |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                               | 1.26E-01                                           |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                               | 1.46E-05                                           |
| $K_{ow}$ (unitless)                 | --                                                                                                                                                                     | NA                                                 |
| $K_{oc}$ (mL/g)                     | --                                                                                                                                                                     | NA                                                 |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was obtained from U.S. EPA (1996b), which provides pH-based values that were estimated by using the MINTEQ2 geochemical speciation model.                 | 16 at pH=4.9;<br>65 at pH=6.8;<br>1,900 at pH=8.0; |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f). | 16 at pH=4.9;<br>65 at pH=6.8;<br>1,900 at pH=8.0; |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f). | 16 at pH=4.9;<br>65 at pH=6.8;<br>1,900 at pH=8.0; |
| $ksg$ (year) <sup>-1</sup>          | --                                                                                                                                                                     | ND                                                 |
| $F_v$ (unitless)                    | Because they are nonvolatile, metals are assumed to be 100 percent in particulate phase and zero percent in the vapor phase, as cited in U.S. EPA (1994f).             | 0.0                                                |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 138.12                         |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 342.1                          |
| $V_p$ (atm)                         | $V_p$ value cited in Montgomery and Welcom (1991).                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 1.07E-05<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in Montgomery and Welcom (1991).                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.26E+03                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.17E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.29E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.81E-06                       |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 7.08E+01                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 3.93E+01                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.93E-01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.95E+00                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.57E+00                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                            |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.00                           |

| S (mg/L)                            | S value cited in Montgomery and Welcom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 8.90E+02                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant.                                                                                                                                                                                                                                                                                                                                                                                | 1.65E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 7.11E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 8.23E-06                       |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 2.34E+01                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 1.66E+01                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.66E-01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.24E+00                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 6.62E-01                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                            |
| $F_v$ (unitless)                    | $F_v$ value was assumed to be 1.0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 1.0                            |

| MW (g/mole)                         | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 138.12   |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 419.10   |
| $V_p$ (atm)                         | --                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | ND       |
| S (mg/L)                            | S value cited in Montgomery and Welcom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 1.07E-05 |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant.                                                                                                                                                                                                                                                                                                                                                                                | 1.65E-06 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.31E-02 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.75E-06 |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 2.46E+01 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 1.72E+01 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.72E-01 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.29E+00 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 6.89E-01 |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0      |
| $F_v$ (unitless)                    | $F_v$ value was assumed to be 1.0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 1.0      |

## CHEMICAL-SPECIFIC INPUTS FOR NITROBENZENE (98-95-3)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 123.11                          |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 279.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 3.21E-04<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.92E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                     | 2.06E-05                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database, U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                              | 5.43E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database, U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                              | 9.43E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 6.80E+01                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.19E+02                        |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.19E+00                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.93E+00                        |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 4.76E+004                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.28E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the liquid-phase $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                         | 1.0                             |

Note:

NA= Not applicable

ND= No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

TABLE A-2-150

## CHEMICAL-SPECIFIC INPUTS FOR 2-NITROPHENOL (88-75-5)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value                       |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 139.11                      |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 317.1                       |
| $V_p$ (atm)                         | $V_p$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 2.63E-04<br>at 25°C (solid) |
| $S$ (mg/L)                          | $S$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 2.50E+03                    |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.46E-05                    |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.44E-02                    |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.19E-06                    |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 6.17E+01                    |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 3.53E+01                    |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.53E-01                    |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.65E+00                    |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.41E+00                    |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                    |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.00                        |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 386.1                       |
| $V_p$ (atm)                         | $V_p$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 1.32E-06<br>at 25°C (solid) |
| $S$ (mg/L)                          | $S$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 2.50E+04                    |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 7.32E-09                    |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.30E-02                    |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.61E-06                    |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 8.13E+01                    |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 4.37E+01                    |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 4.37E-01                    |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.28E+00                    |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.75E+00                    |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 2.09E+02                    |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.00                        |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                     |
| $MW$ (g/mole)                       | $MW$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 158.20              |
| $T_m$ (K)                           | --                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | NA                  |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 3.80E-04<br>at 25°C |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 1.10E+03            |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 5.47E-05            |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 6.50E-02            |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 7.52E-06            |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995)                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 2.57E+02            |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 1.07E+02            |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.07E+00            |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.05E+00            |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 4.29E+00            |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 7.44E+00            |
| $F_v$ (unitless)                    | $F_v$ value cited in NC DEHNR (1997).                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 1.0                 |

| $MW$ (g/mole)                       | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 198.23                                  |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 339.6                                   |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.32E-04<br>at 25°C<br>(solid)          |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 3.74E+01                                |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.99E-04                                |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.12E-02                                |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.35E-06                                |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.06E+03                                |
| $K_{oc}$ (mL/g)                     | Estimated value was obtained from U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 3.27E+02, for pH range of 4.9<br>to 8.0 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.27E+00                                |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.45E+01                                |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.31E+01                                |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 7.44E+00                                |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.0                                     |

| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.63E-03<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.46E+04                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 4.13E-05                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 5.67E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.75E-06                        |
| $K_{ow}$ (unitless)                 | $K_{ow}$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 2.40E+01                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 1.70E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.70E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.28E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 6.80E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991)                                                                                                                                                                                                                                                                                                                                                                     | 1.41E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.00                            |

| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 7.00E-09                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.06E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 3.69E-07                       |
| $K_{ow}$ (unitless)                 | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 3.89E+07                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a; 1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                                         | 2.40E+07                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.40E+05                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.80E+06                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 9.60E+05                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 1.09E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 0.0017                         |

| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.90E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.48E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 3.78E-06                       |
| $K_{ow}$ (unitless)                 | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 6.03E+08                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 3.72E+08                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.72E+06                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.79E+07                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 1.49E+07                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 1.10E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 1.67E-03                       |

| $S$ (mg/L)                          | Homologue group average value obtained from U.S. EPA (1994a).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 1.20E-04                       |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 2.60E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.21E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.38E-06                       |
| $K_{ow}$ (unitless)                 | U.S. EPA (1992d)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 4.37E+06                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 2.69E+06                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.69E+04                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.02E+05                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 1.08E+05                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                            |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 2.19E-01                       |

| $MW$ (g/mole)                       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 340.42                         |
| $T_m$ (K)                           | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 498.1                          |
| $V_p$ (atm)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 3.58E-12<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Homologue group average value obtained from U.S. EPA (1994a).                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 2.40E-04                       |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 6.20E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated by using Equation A-3-2. Recommended value was calculated by using the $MW$ and $D_a$ values that are provided in the tables in Appendix A-2 for 2,3,7,8-TCDF.                                                                                                                                                                                                                                                                                                                       | 1.70E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.51E-06                       |
| $K_{ow}$ (unitless)                 | U.S. EPA (1992d)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 6.17E+06                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 3.80E+06                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.80E+04                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.85E+05                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 1.52E+05                       |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value assumed to be the same as the $ksg$ value calculated for 2,3,4,7,8-PentaCDF. $ksg$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                           | 3.57E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 3.64E-01                       |

| $MW$ (g/mole)                       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 340.42                         |
| $T_m$ (K)                           | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 469.1                          |
| $V_p$ (atm)                         | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 4.33E-12<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 2.36E-04                       |
| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 6.20E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated by using Equation A-3-2. Recommended value was calculated by using the $MW$ and $D_a$ values that are provided in the tables in Appendix A-2 for 2,3,7,8-TCDF.                                                                                                                                                                                                                                                                                                                       | 1.70E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.51E-06                       |
| $K_{ow}$ (unitless)                 | U.S. EPA (1992d)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 8.32E+06                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a) and U.S. EPA (1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                           | 5.13E+06                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 5.13E+04                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.85E+05                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 2.05E+05                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 3.57E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 2.63E-01                       |

| $MW$ (g/mole)                       | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 250.34                         |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 358.1                          |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994f)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 3.10E-06<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994f)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 3.20E-02                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.43E-02                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.86E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.34E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.22E+05                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.21E+04                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.21E+02                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.41E+03                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.29E+03                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 7.33E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.0                            |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                               |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 295.36                        |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 417.1                         |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994f). U.S. EPA (1994c) cites value from Howard (1989-1993)                                                                                                                                                                                                                                                                                                                                                                                                            | 3.1E-06<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994f); U.S. EPA (1994c) cites value from Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                     | 3.20E-02                      |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt, (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                    | 2.86E-02                      |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database, U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                              | 1.87E-02                      |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database, U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                              | 5.0E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994f).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.37E+04                      |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                    | 5.89E+03                      |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 5.89E+01                      |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 4.42E+02                      |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 2.36E+02                      |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 3.62E-01                      |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.0                           |

| H (atm·m <sup>3</sup> /mol)         | H value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S and V <sub>p</sub> values that are provided in this table.                                                                                                                                                                                                                                                        | 1.41E-05                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |    |                 |   |        |   |        |   |        |   |        |   |       |   |       |   |       |   |       |   |       |    |       |    |       |    |       |    |       |    |       |
| D <sub>a</sub> (cm <sup>2</sup> /s) | D <sub>a</sub> value was obtained from CHEMDAT8 database, U.S. EPA (1994d).                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.56E-02                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |    |                 |   |        |   |        |   |        |   |        |   |       |   |       |   |       |   |       |   |       |    |       |    |       |    |       |    |       |    |       |

| Kd <sub>s</sub> (mL/g)              | Kd <sub>s</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate Kd <sub>s</sub> , because the value varies, depending on the fraction of organic carbon in soil. Recommended Kd <sub>s</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table. | <table><tr><th>pH</th><th>K<sub>oc</sub></th></tr><tr><td>1</td><td>199.5</td></tr><tr><td>2</td><td>199.2</td></tr><tr><td>3</td><td>196.0</td></tr><tr><td>4</td><td>169.4</td></tr><tr><td>5</td><td>73.33</td></tr><tr><td>6</td><td>14.17</td></tr><tr><td>7</td><td>5.05</td></tr><tr><td>8</td><td>4.09</td></tr><tr><td>9</td><td>3.99</td></tr><tr><td>10</td><td>3.98</td></tr><tr><td>11</td><td>3.98</td></tr><tr><td>12</td><td>3.98</td></tr><tr><td>13</td><td>3.98</td></tr><tr><td>14</td><td>3.98</td></tr></table>             | pH | K <sub>oc</sub> | 1 | 199.5  | 2 | 199.2  | 3 | 196.0  | 4 | 169.4  | 5 | 73.33 | 6 | 14.17 | 7 | 5.05  | 8 | 4.09  | 9 | 3.99  | 10 | 3.98  | 11 | 3.98  | 12 | 3.98  | 13 | 3.98  | 14 | 3.98  |

| <b>Chemical/Physical Properties (Continued)</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                      |
| $Kd_{sw}$ (L/Kg)                                | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | <p>pH <math>K_{oc}</math></p> <p>1 1,496</p> <p>2 1,494</p> <p>3 1,470</p> <p>4 1,271</p> <p>5 550.0</p> <p>6 106.2</p> <p>7 37.87</p> <p>8 30.66</p> <p>9 29.93</p> <p>10 29.86</p> <p>11 29.85</p> <p>12 29.85</p> <p>13 29.85</p> <p>14 29.85</p> |
| $Kd_{bs}$ (mL/g)                                | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | <p>pH <math>K_{oc}</math></p> <p>1 798.0</p> <p>2 796.7</p> <p>3 784.1</p> <p>4 677.7</p> <p>5 293.3</p> <p>6 56.67</p> <p>7 20.20</p> <p>8 16.35</p> <p>9 15.96</p> <p>10 15.92</p> <p>11 15.92</p> <p>12 15.92</p> <p>13 15.92</p> <p>14 15.92</p> |
| $k_{sg}$ (year) <sup>-1</sup>                   | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.42E+00                                                                                                                                                                                                                                             |
| $F_v$ (unitless)                                | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.0                                                                                                                                                                                                                                                  |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 178.22                         |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 371.1                          |
| $V_p$ (atm)                         | Geometric mean value calculated from values cited in Montgomery and Welkom (1991).                                                                                                                                                                                                                                                                                                                                                                                                                              | 1.35E-03<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in Lucius et al. (1992).                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 1.28E+00                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.88E-01                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.33E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.47E-06                       |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 3.55E+04                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 2.09E+04                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.09E+02                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.57E+03                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 8.35E+02                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.26E+00                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 1.00                           |

Note:

NA = Not applicable

ND = No data available

| H (atm·m <sup>3</sup> /mol)           | H value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S, and V <sub>p</sub> values that are provided in this table.                                                                                                                                                                                                                                                                                                     | 5.95E-07                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                 |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |    |      |    |      |
| D <sub>a</sub> (cm <sup>2</sup> /s)   | D <sub>a</sub> value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 8.27E-02                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                 |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |    |      |    |      |
| D <sub>w</sub> (cm <sup>2</sup> /s)   | D <sub>w</sub> value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 1.03E-05                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                 |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |    |      |    |      |

| Kd <sub>s</sub> (cm <sup>3</sup> /g)  | Kd <sub>s</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate Kd <sub>s</sub> , because the value varies, depending on the fraction of organic carbon in soil. Kd <sub>s</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table.                                                           | 2.20E-01                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                 |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |    |      |    |      |
| Kd <sub>sw</sub> (L/Kg)               | Kd <sub>sw</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate Kd <sub>sw</sub> , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended Kd <sub>sw</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table. | 1.65E+00                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                 |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |    |      |    |      |
| Kd <sub>bs</sub> (cm <sup>3</sup> /g) | Kd <sub>bs</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate Kd <sub>bs</sub> , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended Kd <sub>bs</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table.           | 8.79E-01                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                 |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |    |      |    |      |
| ksg (year) <sup>-1</sup>              | ksg value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                                                            | 2.53E+01                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                 |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |    |      |    |      |

## CHEMICAL-SPECIFIC INPUTS FOR PHENOL (108-95-2)

(Page 2 of 2)

| Parameter            | Reference and Explanation                                                                                                                                                                                                                                                                                                                     | Value |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| <i>Fv</i> (unitless) | <i>Fv</i> value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of <i>Fv</i> was calculated by using <i>T<sub>m</sub></i> and <i>Vp</i> values that are provided in this table. <i>Vp</i> value for this compound was converted to a liquid-phase value before being used in the calculations. | 1.0   |

Note:

NA= Not applicable

ND= No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 260.4                           |
| $T_m$ (K)                           | --                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | ND                              |
| $V_p$ (atm)                         | $V_p$ value cited in Montgomery and Welkom (1991).                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 1.70E-06<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 3.80E+01                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.16E-05                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.05E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 5.88E-06                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 6.46E+03                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 1.33E+03                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.33E+01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 9.96E+01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 5.31E+01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be zero due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 0.0                             |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.00                            |

Note:

NA = Not applicable

ND = No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

TABLE A-2-166

## CHEMICAL-SPECIFIC INPUTS FOR PHTHALIC ANHYDRIDE (85-44-9)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value                          |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 148.11                         |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 403.9                          |
| $V_p$ (atm)                         | Howard (1989-1993)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 2.63E-07<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Howard (1989-1993)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 6.20E+03                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.28E-09                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.04E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.97E-06                       |
| $K_{ow}$ (unitless)                 | NC DEHNR (1997)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.5E-01                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 2.10E-01                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.10E-03                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.57E-02                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 8.40E-03                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.35E+04                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 1.0                            |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 256.13                         |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 428.1                          |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 5.30E-07<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 1.50E+01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 9.05E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.71E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 5.45E-06                       |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995)                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 3.24E+03                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 7.74E+02                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 7.74E+00                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 5.81E+01                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 3.10E+01                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                            |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.0                            |

Note:

NA = Not applicable

ND = No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 202.24                         |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 429.1                          |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 5.59E-09<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.37E-01                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 8.25E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.72E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.14E-06                       |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.00E+05                       |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.80E+04                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 6.80E+02                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 5.10E+03                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 2.72E+03                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992)                                                                                                                                                                                                                                                                                                                                                                                                  | 1.33E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 0.9946                         |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 79.10                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 231.5                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 2.60E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 3.00E+02                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.86E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.10E-01                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.08E-05                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995)                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 4.68E+00                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 4.72E+00                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 4.72E-02                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.54E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.89E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 3.61E+01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $V_p$ (atm)                         | --                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | ND       |
| $S$ (mg/L)                          | --                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | ND       |
| $H$ (atm·m <sup>3</sup> /mol)       | --                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | ND       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.05E-02 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.69E-06 |
| $K_{ow}$ (unitless)                 | Recommended $K_{ow}$ value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.17E+05 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 1.28E+04 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.28E+02 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 9.56E+02 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 5.10E+02 |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0      |
| $F_v$ (unitless)                    | $F_v$ value was assumed to be 1.0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 1.0      |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neill, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 162.18                          |
| $T_m$ (K)                           | Budavari, O'Neill, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 284.1                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.10E-04<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.50E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.19E-05                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                           | 4.06E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                           | 7.16E-06                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 4.57E+02                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 1.68E+02                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.68E+00                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.26E+01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 6.73E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                          | 78.96                                            |
| $T_m$ (°K)                          | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                          | 490.1                                            |
| $V_p$ (atm)                         | All metals, except mercury, are assumed to be nonvolatile at ambient temperatures.                                                                                     | 0.0                                              |
| $S$ (mg/L)                          | All metals, except mercury, are assumed to be insoluble in water.                                                                                                      | 0.0                                              |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value is assumed to be zero, because the $V_p$ and $S$ values are zero for all metals, except mercury.                                                             | 0.0                                              |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                               | 1.03E-01                                         |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                               | 1.20E-05                                         |
| $K_{ow}$ (unitless)                 | --                                                                                                                                                                     | NA                                               |
| $K_{oc}$ (mL/g)                     |                                                                                                                                                                        | NA                                               |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was obtained from U.S. EPA (1996b), which provides pH-based values that were estimated by using the MINTEQ2 geochemical speciation model.                 | 18 at pH=4.9;<br>5.0 at pH=6.8;<br>2.2 at pH=8.0 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f). | 18 at pH=4.9;<br>5.0 at pH=6.8;<br>2.2 at pH=8.0 |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f). | 18 at pH=4.9;<br>5.0 at pH=6.8;<br>2.2 at pH=8.0 |
| $k_{sg}$ (year) <sup>-1</sup>       | --                                                                                                                                                                     | ND                                               |
| $F_v$ (unitless)                    | Because they are nonvolatile, metals are assumed to be 100 percent in particulate phase and zero percent in the vapor phase, as cited in U.S. EPA (1994f).             | 0.0                                              |

| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 2.20E-13<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 1.50E+02                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 4.90E-13                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.38E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 5.58E-06                       |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 8.51E+01                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 4.53E+01                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 4.53E-01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.40E+00                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 1.81E+00                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991)                                                                                                                                                                                                                                                                                                                                                                     | 9.03E+00                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                          | 0.086                          |

| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 8.21E-03<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.57E+02                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 3.33E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.73E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.77E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 8.49E+02                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.12E+02                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 9.12E+00                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 6.84E+01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 3.65E+01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.60E-05                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.27E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.81E-06                       |
| $K_{ow}$ (unitless)                 | U.S. EPA (1994a)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 4.37E+06                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a; 1994b). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                                         | 2.69E+06                       |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.69E+04                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.02E+05                       |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.08E+05                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 4.29E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $S$ , $T_m$ , and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                          | 0.4901                         |

| $H$ (atm·m <sup>3</sup> /mol)       | U.S. EPA (1994a).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.60E-06                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                           | 1.79E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                                                                                                                                                                                                                                                                                                                                                                        | 4.85E-06                       |
| $K_{ow}$ (unitless)                 | U.S. EPA (1992d)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 3.39E+06                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for dioxins and furans that is cited in U.S. EPA (1994a; 1994c). Recommended value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                                                         | 2.09E+06                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.09E+04                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.57E+05                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.            | 8.36E+04                       |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 3.57E-01                       |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid phase value before being used in the calculations.                                                                                                                                                                                                  | 0.6634                         |

| $Vp$ (atm)                          | $Vp$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 7.1E-06<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.30E+00                      |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $Vp$ values that are provided in this table.                                                                                                                                                                                                                                                                    | 1.18E-03                      |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.11E-02                      |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.75E-06                      |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 4.36E+04                      |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 5.89E+03                      |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 5.89E+01                      |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 4.42E+02                      |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 2.36E+02                      |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                       | 1.41E+00                      |
| $Fv$ (unitless)                     | $Fv$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $Fv$ was calculated by using $S$ , $T_m$ , and $Vp$ values that are provided in this table. $Vp$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                              | 1.0                           |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 167.85                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 230.1                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 1.60E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 1.10E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.44E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.15E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.30E-06                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995)                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 4.27E+02                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 1.59E+02                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.59E+00                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.20E+01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 6.37E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 5.75E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 229.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 6.80E-03<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.07E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 3.72E-04                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.16E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.26E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.40E+04                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.90E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 7.90E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 5.93E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 3.16E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 5.75E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <i>H</i> (atm·m <sup>3</sup> /mol)                     | <i>H</i> value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the <i>MW</i> , <i>S</i> , and <i>V<sub>p</sub></i> values that are provided in this table.                                                                                                                                                                                                                                                                                                                                       | 1.73E-02                        |
| <i>D<sub>a</sub></i> (cm <sup>2</sup> /s)              | <i>D<sub>a</sub></i> value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 7.20E-02                        |
| <i>D<sub>w</sub></i> (cm <sup>2</sup> /s)              | <i>D<sub>w</sub></i> value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 8.20E-06                        |
| <i>K<sub>ow</sub></i> (unitless)                       | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 3.51E+02                        |
| <i>K<sub>oc</sub></i> (mL/g)                           | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.65E+02                        |
| <i>K<sub>d<sub>s</sub></sub></i> (cm <sup>3</sup> /g)  | <i>K<sub>d<sub>s</sub></sub></i> value was calculated by using the correlation equation with <i>K<sub>oc</sub></i> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate <i>K<sub>d<sub>s</sub></sub></i> , because the value varies, depending on the fraction of organic carbon in soil. Recommended <i>K<sub>d<sub>s</sub></sub></i> value was calculated by using the <i>K<sub>oc</sub></i> value that is provided in this table.                                               | 2.65E+00                        |
| <i>K<sub>d<sub>sw</sub></sub></i> (L/Kg)               | <i>K<sub>d<sub>sw</sub></sub></i> value was calculated by using the correlation equation with <i>K<sub>oc</sub></i> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate <i>K<sub>d<sub>sw</sub></sub></i> , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended <i>K<sub>d<sub>sw</sub></sub></i> value was calculated by using the <i>K<sub>oc</sub></i> value that is provided in this table. | 1.99E+01                        |
| <i>K<sub>d<sub>bs</sub></sub></i> (cm <sup>3</sup> /g) | <i>K<sub>d<sub>bs</sub></sub></i> value was calculated by using the correlation equation with <i>K<sub>oc</sub></i> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate <i>K<sub>d<sub>bs</sub></sub></i> , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended <i>K<sub>d<sub>bs</sub></sub></i> value was calculated by using the <i>K<sub>oc</sub></i> value that is provided in this table.           | 1.06E+01                        |
| <i>k<sub>sg</sub></i> (year) <sup>-1</sup>             | <i>k<sub>sg</sub></i> value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 7.03E-01                        |
| <i>F<sub>v</sub></i> (unitless)                        | <i>F<sub>v</sub></i> value was calculated by using the equation cited in Junge (1977). Recommended value of <i>F<sub>v</sub></i> was calculated by using the <i>V<sub>p</sub></i> value that is provided in this table.                                                                                                                                                                                                                                                                                                                                                                                           | 1.0                             |

| H (atm·m <sup>3</sup> /mol)           | H value was calculated by using the theoretical equation from, Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S, and V <sub>p</sub> values that are provided in this table.                                                                                                                                                                                                                                                                                                                    | 1.53E-05                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |    |       |    |       |    |       |    |       |

| Kd <sub>s</sub> (cm <sup>3</sup> /g)  | Kd <sub>s</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate Kd <sub>s</sub> , because the value varies, depending on the fraction of organic carbon in soil. Recommended Kd <sub>s</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table for a pH of 7.0.                                               | 2.49                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |    |       |    |       |    |       |    |       |
| Kd <sub>sw</sub> (L/Kg)               | Kd <sub>sw</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate Kd <sub>sw</sub> , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended Kd <sub>sw</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table for a pH of 7.0. | 18.69                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |    |       |    |       |    |       |    |       |
| Kd <sub>bs</sub> (cm <sup>3</sup> /g) | Kd <sub>bs</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate Kd <sub>bs</sub> , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended Kd <sub>bs</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table for a pH of 7.0.                   | 9.97                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |    |       |    |       |    |       |    |       |
| ksg (year) <sup>-1</sup>              | Ksg value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.41                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |    |       |    |       |    |       |    |       |

| Parameter            | Reference and Explanation                                                                                                                                                                                                                                                                                                                                  | Value |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| <i>Fv</i> (unitless) | <i>Fv</i> value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of <i>Fv</i> was calculated by using <i>S</i> , <i>T<sub>m</sub></i> , and <i>Vp</i> values that are provided in this table. <i>Vp</i> value for this compound was converted to a liquid-phase value before being used in the calculations. | 1.0   |

Note:

NA = Not applicable

ND = No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1994b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.00E+06                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.54E-05                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.31E-01                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.07E-05                        |
| $K_{ow}$ (unitless)                 | Value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 2.80E+00                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 3.16E+00                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.16E-02                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.37E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.26E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                          | 4.43E+01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.00                            |

TABLE A-2-184

## CHEMICAL-SPECIFIC INPUTS FOR THALLIUM (7440-28-0)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                              | Value                                          |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| <b>Chemical/Physical Properties</b> |                                                                                                                                                                        |                                                |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                          | 204.38                                         |
| $T_m$ (°K)                          | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                          | 576.6                                          |
| $V_p$ (atm)                         | All metals, except mercury, are assumed to be nonvolatile at ambient temperatures.                                                                                     | 0.0                                            |
| $S$ (mg/L)                          | All metals, except mercury, are assumed to be insoluble in water.                                                                                                      | 0.0                                            |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value is assumed to be zero, because the $V_p$ and $S$ values are zero for all metals, except mercury.                                                             | 0.0                                            |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                               | 5.48E-02                                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                               | 6.34E-06                                       |
| $K_{ow}$ (unitless)                 | --                                                                                                                                                                     | NA                                             |
| $K_{oc}$ (mL/g)                     | --                                                                                                                                                                     | NA                                             |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was obtained from U.S. EPA (1996b), which provides pH-based values that were estimated by using the MINTEQ2 geochemical speciation model.                 | 44 at pH=4.9;<br>71 at pH=6.8;<br>96 at pH=8.0 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f). | 44 at pH=4.9;<br>71 at pH=6.8;<br>96 at pH=8.0 |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f). | 44 at pH=4.9;<br>71 at pH=6.8;<br>96 at pH=8.0 |
| $k_{sg}$ (year) <sup>-1</sup>       | --                                                                                                                                                                     | ND                                             |
| $F_v$ (unitless)                    | Because they are nonvolatile, metals are assumed to be 100 percent in particulate phase and zero percent in the vapor phase, as cited in U.S. EPA (1994f).             | 0.0                                            |

TABLE A-2-185

## CHEMICAL-SPECIFIC INPUTS FOR TOLUENE (108-88-3)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 92.13                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 178.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 3.71E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 5.58E+02                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.13E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.72E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.23E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 4.65E+02                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.40E+02                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.40E+00                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.05E+01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 5.60E+00                        |
| $ksg$ (year) <sup>-1</sup>          | $ksg$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991) and Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                       | 1.15E+01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neill, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 107.15                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 258.4                           |
| $Vp$ (atm)                          | $Vp$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 3.94E-04<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.74E+04                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $Vp$ values that are provided in this table.                                                                                                                                                                                                                                                                    | 2.43E-06                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.14E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.12E-06                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 2.19E+01                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 1.57E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.57E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.18E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 6.28E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 3.61E+01                        |
| $Fv$ (unitless)                     | $Fv$ value was calculated by using the equation cited in Junge (1977). Recommended value of $Fv$ was calculated by using the $Vp$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                         | 1.0                             |

| $V_p$ (atm)                         | Geometric mean value calculated from values cited in Mackay, Shiu, and Ma (1991).                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.20E-04<br>at 25°C (solid) |
| $S$ (mg/L)                          | Geometric mean value calculated from values cited in Mackay, Shiu, and Ma (1991).                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.05E+01                    |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.84E-03                    |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.02E-02                    |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.15E-06                    |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1.11E+04                    |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 2.02E+03                    |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.02E+01                    |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.52E+02                    |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 8.10E+01                    |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 1.41E+00                    |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table. $V_p$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                  | 1.00                        |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 181.46                          |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 290.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 4.42E-04<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 3.07E+01                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 2.61E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.00E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.23E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 9.73E+03                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.66E+03                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.66E+01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.24E+02                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 6.64E+01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991) and Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                              |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 133.42                       |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 242.7                        |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.63E-01<br>at 25°C (liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.17E+03                     |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.86E-02                     |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.66E-02                     |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.56E-06                     |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 2.64E+02                     |
| $K_{oc}$ (mL/g)                     | Geometric mean value cited in U.S. EPA (1996b)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 1.35E+05                     |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.35E+03                     |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.01E+04                     |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 5.40E+03                     |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.26E-01                     |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.00                         |

| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 238.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.31E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 4.40E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.00E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.51E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.0E-05                         |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.25E+02                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.50E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 7.50E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 5.63E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 3.00E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 6.93E-01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 131.40                          |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 188.3                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 9.48E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.18E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.06E-02                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.65E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.94E-06                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.71E+02                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 9.40E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 9.40E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 7.05E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 3.76E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 0.703                           |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 137.38                          |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 162.1                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.10E+00<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.10E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 1.37E-01                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 4.27E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.0E-05                         |
| $K_{ow}$ (unitless)                 | $K_{ow}$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 3.40E+02                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 1.34E+02                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.34E+00                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.00E+01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 5.34E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 7.03E-01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

Note:

NA = Not applicable

ND = No data available

| H (atm·m <sup>3</sup> /mol)           | H value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S, and V <sub>p</sub> values that are provided in this table.                                                                                                                                                                                                                                                                                                                     | 5.64E-06                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |
| D <sub>a</sub> (cm <sup>2</sup> /s)   | D <sub>a</sub> value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 2.91E-02                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |

| Kd <sub>s</sub> (cm <sup>3</sup> /g)  | Kd <sub>s</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate Kd <sub>s</sub> , because the value varies, depending on the fraction of organic carbon in soil. Kd <sub>s</sub> value calculated using the K <sub>oc</sub> value that is provided in this table for a pH of 7.0.                                                                  | 1.13E+01                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |
| Kd <sub>sw</sub> (L/Kg)               | Kd <sub>sw</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate Kd <sub>sw</sub> , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended Kd <sub>sw</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table for a pH of 7.0. | 8.45E+01                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |
| Kd <sub>bs</sub> (cm <sup>3</sup> /g) | Kd <sub>bs</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate Kd <sub>bs</sub> , because the value varies depending on the fraction of organic fraction in bottom sediment. Kd <sub>bs</sub> value calculated using the K <sub>oc</sub> value that is provided in this table for a pH of 7.0.                                      | 4.51E+01                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |
| k <sub>sg</sub> (year) <sup>-1</sup>  | k <sub>sg</sub> value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                                                                | 0.367                                                                                                                                                                                                                                                                                                                                                                                                 |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |
| F <sub>v</sub> (unitless)             | F <sub>v</sub> value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of F <sub>v</sub> was calculated by using S, T <sub>m</sub> , and V <sub>p</sub> values that are provided in this table. V <sub>p</sub> value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                                   | 1.0                                                                                                                                                                                                                                                                                                                                                                                                   |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |

| H (atm·m <sup>3</sup> /mol)           | H value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S, and V <sub>p</sub> values that are provided in this table.                                                                                                                                                                                                                                                                                                                     | 4.06E-06                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |

| K <sub>oc</sub> (mL/g)                | For all ionizing organics, K <sub>oc</sub> values were estimated on the basis of pH. Estimated values were obtained from U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                         | <table><tr><td>pH</td><td>K<sub>oc</sub></td></tr><tr><td>1</td><td>1,070</td></tr><tr><td>2</td><td>1,070</td></tr><tr><td>3</td><td>1,069</td></tr><tr><td>4</td><td>1,063</td></tr><tr><td>5</td><td>1,006</td></tr><tr><td>6</td><td>670.8</td></tr><tr><td>7</td><td>226.2</td></tr><tr><td>8</td><td>120.4</td></tr><tr><td>9</td><td>108.4</td></tr><tr><td>10</td><td>107.1</td></tr></table> | pH | K <sub>oc</sub> | 1 | 1,070 | 2 | 1,070 | 3 | 1,069 | 4 | 1,063 | 5 | 1,006 | 6 | 670.8 | 7 | 226.2 | 8 | 120.4 | 9 | 108.4 | 10 | 107.1 |

| Kd <sub>s</sub> (cm <sup>3</sup> /g)  | Kd <sub>s</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate Kd <sub>s</sub> , because the value varies, depending on the fraction of organic carbon in soil. Kd <sub>s</sub> value calculated using the K <sub>oc</sub> value that is provided in this table for a pH of 7.0.                                                                  | 2.26E+00                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |
| Kd <sub>sw</sub> (L/Kg)               | Kd <sub>sw</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate Kd <sub>sw</sub> , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended Kd <sub>sw</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table for a pH of 7.0. | 1.70E+01                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |
| Kd <sub>bs</sub> (cm <sup>3</sup> /g) | Kd <sub>bs</sub> value was calculated by using the correlation equation with K <sub>oc</sub> that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate Kd <sub>bs</sub> , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended Kd <sub>bs</sub> value was calculated by using the K <sub>oc</sub> value that is provided in this table for a pH of 7.0.                   | 9.05E+00                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |
| k <sub>sg</sub> (year) <sup>-1</sup>  | K <sub>sg</sub> value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                                                                | 3.61E+00                                                                                                                                                                                                                                                                                                                                                                                              |    |                 |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |   |       |    |       |

## CHEMICAL-SPECIFIC INPUTS FOR 2,4,6-TRICHLOROPHENOL (88-06-2)

(Page 2 of 2)

| Parameter            | Reference and Explanation                                                                                                                                                                                                                                                                                                                                  | Value |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| <i>Fv</i> (unitless) | <i>Fv</i> value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of <i>Fv</i> was calculated by using <i>S</i> , <i>T<sub>m</sub></i> , and <i>Vp</i> values that are provided in this table. <i>Vp</i> value for this compound was converted to a liquid-phase value before being used in the calculations. | 1.0   |

Note:

NA = Not applicable

ND = No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 4.90E-03<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.90E+03                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 3.80E-04                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.99E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.24E-06                        |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1.78E+02                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 8.05E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 8.10E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 6.04E+00                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 3.22E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $k_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 7.03E-01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 120.19                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 287.9                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1992a).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.30E-03<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1992a).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 2.00E+01                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 7.81E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 6.48E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.86E-06                        |
| $K_{ow}$ (unitless)                 | $K_{ow}$ value cited in Howard (1989-1993).                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 2.63E+03                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 1.67E+03                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.67E+01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.25E+02                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 6.69E+01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Mackay, Shiu, and Ma (1992).                                                                                                                                                                                                                                                                                                                                                                                                 | 3.16E+01                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.00                            |

| $MW$ (g/mole)                       | Budavari, O'Neill, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 213.11                         |
| $T_m$ (K)                           | Budavari, O'Neill, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 395.6                          |
| $Vp$ (atm)                          | $Vp$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 1.30E-07<br>at 25°C<br>(solid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1995b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 3.20E+02                       |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $Vp$ values that are provided in this table.                                                                                                                                                                                                                                                                    | 8.66E-08                       |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                           | 2.84E-02                       |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from WATER8 model database (U.S. EPA 1995d).                                                                                                                                                                                                                                                                                                                                                                                                                                           | 6.08E-06                       |
| $K_{ow}$ (unitless)                 | Arithmetic mean value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 1.51E+01                       |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 1.18E+01                       |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.18E-01                       |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.84E-01                       |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 4.72E-01                       |
| $ksg$ (year) <sup>-1</sup>          | $Ksg$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 0.0                            |
| $Fv$ (unitless)                     | $Fv$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $Fv$ was calculated by using $S$ , $T_m$ , and $Vp$ values that are provided in this table. $Vp$ value for this compound was converted to a liquid-phase value before being used in the calculations.                                                                                                                                                                                              | 1.0                            |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |          |
| MW (g/mole)                         | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 227.13   |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 353.2    |
| $V_p$ (atm)                         | Value cited in U.S. EPA (1994b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 2.63E-07 |
| S (mg/L)                            | Value cited in U.S. EPA (1994b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1.30E+02 |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the MW, S, and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                         | 4.59E-07 |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.62E-02 |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 5.85E-06 |
| $K_{ow}$ (unitless)                 | Recommended $K_{ow}$ value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.98E+01 |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for phthalates and PAHs, / all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                | 2.51E+01 |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.51E-01 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.88E+00 |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.00E+00 |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991)                                                                                                                                                                                                                                                                                                                                                                     | 1.41E+00 |
| Fv (unitless)                       | Fv value was assumed to be 1.0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 0.9980   |

Note:

NA = Not applicable

ND = No data available

All parameters are defined in LIST OF VARIABLES on page A-2-ii.

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 86.09                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 180.1                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.43E-01<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 2.24E+04                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 5.50E-04                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 9.94E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.00E-05                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 5.00E+00                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans, cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                       | 4.97E+00                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 4.97E-02                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 3.73E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.99E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was assumed to be 0 due to a lack of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 0.0                             |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 62.50                           |
| $T_m$ (K)                           | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 119.3                           |
| $V_p$ (atm)                         | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 3.68E+00<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 7.30E+02                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 3.15E-01                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.58E-01                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.19E-05                        |
| $K_{ow}$ (unitless)                 | Geometric mean value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.40E+01                        |
| $K_{oc}$ (mL/g)                     | $K_{oc}$ value was calculated by using the correlation equation with $K_{ow}$ for all nonionizing organics except phthalates, PAHs, dioxins, and furans as cited in U.S. EPA (1994c). $K_{oc}$ value was calculated by using the recommended $K_{ow}$ value that is provided in this table.                                                                                                                                                                                                                     | 1.11E+01                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed fraction organic carbon of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.11E-01                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 8.32E-01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies depending on the fraction of organic fraction in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.                   | 4.44E-01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 1.41E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in this table.                                                                                                                                                                                                                                                                                                                                      | 1.0                             |

| <b>Chemical/Physical Properties</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                 |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 106.16                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 225.7                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.06E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.86E+02                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.05E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.69E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.49E-06                        |
| $K_{ow}$ (unitless)                 | Recommended $K_{ow}$ value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.59E+03                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1.96E+02                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 1.96E+00                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.47E+01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 7.84E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.000                           |

| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 248.1                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.06E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.86E+02                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.05E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.69E-02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.44E-06                        |
| $K_{ow}$ (unitless)                 | Recommended $K_{ow}$ value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.35E+03                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 2.41E+02                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 2.41E+00                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 1.81E+01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 9.64E+00                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using the equation cited in Junge (1977). Recommended value of $F_v$ was calculated by using the $V_p$ value that is provided in the table.                                                                                                                                                                                                                                                                                                                                       | 1.000                           |

| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | 106.16                          |
| $T_m$ (K)                           | Montgomery and Welkom (1991)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 286.1                           |
| $V_p$ (atm)                         | $V_p$ value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 1.06E-02<br>at 25°C<br>(liquid) |
| $S$ (mg/L)                          | $S$ value cited in U.S. EPA (1994c).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1.86E+02                        |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value was calculated by using the theoretical equation from Lyman, Reehl, and Rosenblatt (1982), which defines the constant. Recommended value was calculated by using the $MW$ , $S$ , and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                   | 6.05E-03                        |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 7.61E+02                        |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was obtained from CHEMDAT8 database (U.S. EPA 1994d).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 8.50E-06                        |
| $K_{ow}$ (unitless)                 | Recommended $K_{ow}$ value cited in Karickhoff and Long (1995).                                                                                                                                                                                                                                                                                                                                                                                                                                                 | 1.48E+03                        |
| $K_{oc}$ (mL/g)                     | Geometric mean of measured values obtained from U.S. EPA (1996b).                                                                                                                                                                                                                                                                                                                                                                                                                                               | 3.11E+02                        |
| $Kd_s$ (cm <sup>3</sup> /g)         | $Kd_s$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.01 in soil. Measured organic carbon in soil, specific to site conditions, should be used to calculate $Kd_s$ , because the value varies, depending on the fraction of organic carbon in soil. Recommended $Kd_s$ value was calculated by using the $K_{oc}$ value that is provided in this table.                                                     | 3.11E+00                        |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.075 in suspended sediment. Measured organic carbon in suspended sediment, specific to site conditions, should be used to calculate $Kd_{sw}$ , because the value varies, depending on the fraction of organic carbon in suspended sediment. Recommended $Kd_{sw}$ value was calculated by using the $K_{oc}$ value that is provided in this table. | 2.33E+01                        |
| $Kd_{bs}$ (cm <sup>3</sup> /g)      | $Kd_{bs}$ value was calculated by using the correlation equation with $K_{oc}$ that is cited in U.S. EPA (1993d) for an assumed organic carbon fraction of 0.04 in bottom sediment. Measured organic carbon in bottom sediment, specific to site conditions, should be used to calculate $Kd_{bs}$ , because the value varies, depending on the fraction of organic carbon in bottom sediment. Recommended $Kd_{bs}$ value was calculated by using the $K_{oc}$ value that is provided in this table.           | 1.24E+01                        |
| $k_{sg}$ (year) <sup>-1</sup>       | $K_{sg}$ value was calculated by using the chemical half-life in soil, as cited in Howard, Boethling, Jarvis, Meylan, and Michalenko (1991).                                                                                                                                                                                                                                                                                                                                                                    | 9.03E+00                        |
| $F_v$ (unitless)                    | $F_v$ value was calculated by using equations cited in Junge (1977) and Bidleman (1988). Recommended value of $F_v$ was calculated by using $T_m$ and $V_p$ values that are provided in this table.                                                                                                                                                                                                                                                                                                             | 1.00                            |

TABLE A-2-204

## CHEMICAL-SPECIFIC INPUTS FOR ZINC (7440-66-6)

(Page 1 of 1)

| Parameter                           | Reference and Explanation                                                                                                                                              | Value             |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| <b>Chemical/Physical Properties</b> |                                                                                                                                                                        |                   |
| $MW$ (g/mole)                       | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                          | 65.38             |
| $T_m$ (°K)                          | Budavari, O'Neil, Smith, and Heckelman (1989)                                                                                                                          | 692.6             |
| $V_p$ (atm)                         | All metals, except mercury, are assumed to be nonvolatile at ambient temperatures.                                                                                     | 0.0               |
| $S$ (mg/L)                          | All metals, except mercury, are assumed to be insoluble in water.<br>OR Budavari, O'Neil, Smith, and Heckelman (1989)                                                  | 0.0               |
| $H$ (atm·m <sup>3</sup> /mol)       | $H$ value is assumed to be zero, because the $V_p$ and $S$ values are zero for all metals, except mercury.                                                             | 0.0               |
| $D_a$ (cm <sup>2</sup> /s)          | $D_a$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                               | 1.17E-01          |
| $D_w$ (cm <sup>2</sup> /s)          | $D_w$ value was calculated using the equation cited in U.S. EPA (1996a).                                                                                               | 1.36E-05          |
| $K_{ow}$ (unitless)                 | --                                                                                                                                                                     | NA                |
| $K_{oc}$ (mL/g)                     | --                                                                                                                                                                     | NA                |
| $Kd_s$ (mL/g)                       | $Kd_s$ value was obtained from U.S. EPA (1996b), which provides pH-based values that were estimated by using the MINTEQ2 geochemical speciation model.                 | 6.2E+01 at pH=6.8 |
| $Kd_{sw}$ (L/Kg)                    | $Kd_{sw}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f). | 6.2E+01 at pH=6.8 |
| $Kd_{bs}$ (mL/g)                    | $Kd_{bs}$ value is assumed to be same as the $Kd_s$ value, because organic carbon does not play a major role in sorption for the metals, as cited in U.S. EPA (1994f). | 6.2E+01 at pH=6.8 |
| $k_{sg}$ (year) <sup>-1</sup>       | --                                                                                                                                                                     | ND                |
| $F_v$ (unitless)                    | Because they are nonvolatile, metals are assumed to be 100 percent in particulate phase and zero percent in the vapor phase, as cited in U.S. EPA (1994f).             | 0.0               |

## APPENDIX B

### LIST OF VARIABLES AND PARAMETERS

|               |   |                                                                                                                          |
|---------------|---|--------------------------------------------------------------------------------------------------------------------------|
| $\gamma$      | = | Empirical constant (unitless)                                                                                            |
| $\lambda_z$   | = | Dimensionless viscous sublayer thickness (unitless)                                                                      |
| $\mu_a$       | = | Viscosity of air (g/cm-s)                                                                                                |
| $\mu_w$       | = | Viscosity of water corresponding to water temperature (g/cm-s)                                                           |
| $\rho_a$      | = | Density of air (g/cm <sup>3</sup> or g/m <sup>3</sup> )                                                                  |
| $\rho_w$      | = | Density of water corresponding to water temperature (g/cm <sup>3</sup> )                                                 |
| $\theta$      | = | Temperature correction factor (unitless)                                                                                 |
| $\theta_{bs}$ | = | Bed sediment porosity (L volume/L sediment)—unitless                                                                     |
| $\theta_{sw}$ | = | Soil volumetric water content (mL water/cm <sup>3</sup> soil)                                                            |
| $a$           | = | Empirical intercept coefficient (unitless)                                                                               |
| $A$           | = | Surface area of contaminated area (m <sup>2</sup> )                                                                      |
| $A_I$         | = | Impervious watershed area receiving COPC deposition (m <sup>2</sup> )                                                    |
| $A_L$         | = | Total watershed area receiving COPC deposition (m <sup>2</sup> )                                                         |
| $A_W$         | = | Water body surface area (m <sup>2</sup> )                                                                                |
| $b$           | = | Empirical slope coefficient (unitless)                                                                                   |
| $BD$          | = | Soil bulk density (g soil/cm <sup>3</sup> soil)                                                                          |
| $BCFr$        | = | Plant-soil biotransfer factor (mg COPC/kg DW plant)/(mg COPC/kg soil)—unitless                                           |
| $BS$          | = | Benthic solids concentration (g sediment/cm <sup>3</sup> sediment)                                                       |
| $Bs$          | = | Soil bioavailability factor (unitless)                                                                                   |
| $Bv$          | = | Air-to-plant biotransfer factor (mg COPC/kg DW plant)/(mg COPC/kg air)—unitless                                          |
| $c$           | = | Junge constant = $1.7 \times 10^{-4}$ (atm-cm)                                                                           |
| $C$           | = | USLE cover management factor (unitless)                                                                                  |
| $C_d$         | = | Drag coefficient (unitless)                                                                                              |
| $C_{dw}$      | = | Dissolved phase water concentration (mg COPC/L water)                                                                    |
| $C_{hp}$      | = | Unitized hourly air concentration from vapor phase ( $\mu$ g-s/g-m <sup>3</sup> )                                        |
| $C_{hv}$      | = | Unitized hourly air concentration from particle phase ( $\mu$ g-s/g-m <sup>3</sup> )                                     |
| $C_s$         | = | COPC concentration in soil (mg COPC/kg soil)                                                                             |
| $C_{sed}$     | = | COPC concentration in bed sediment (mg COPC/kg sediment)                                                                 |
| $C_{wctot}$   | = | Total COPC concentration in water column (mg COPC/L water column)                                                        |
| $C_{wtot}$    | = | Total water body COPC concentration including water column and bed sediment (g COPC/m <sup>3</sup> water body) or (mg/L) |
| $Cyp$         | = | Unitized yearly average air concentration from particle phase ( $\mu$ g-s/g-m <sup>3</sup> )                             |
| $Cyv$         | = | Unitized yearly average air concentration from vapor phase ( $\mu$ g-s/g-m <sup>3</sup> )                                |
| $Cyww$        | = | Unitized yearly average air concentration from vapor phase (over water body or watershed) ( $\mu$ g-s/g-m <sup>3</sup> ) |
| $D_a$         | = | Diffusivity of COPC in air (cm <sup>2</sup> /s)                                                                          |
| $d_{bs}$      | = | Depth of upper benthic sediment layer (m)                                                                                |

|           |   |                                                                                                                                  |
|-----------|---|----------------------------------------------------------------------------------------------------------------------------------|
| $D_s$     | = | Deposition term (mg COPC/kg soil-yr)                                                                                             |
| $d_{wc}$  | = | Depth of water column (m)                                                                                                        |
| $D_w$     | = | Diffusivity of COPC in water (cm <sup>2</sup> /s)                                                                                |
| $Dydp$    | = | Unitized yearly average dry deposition from particle phase (s/m <sup>2</sup> -yr)                                                |
| $Dytwp$   | = | Unitized yearly average total (wet and dry) deposition from particle phase (over water body or watershed) (s/m <sup>2</sup> -yr) |
| $Dywp$    | = | Unitized yearly average wet deposition from particle phase (s/m <sup>2</sup> -yr)                                                |
| $Dyww$    | = | Unitized yearly average wet deposition from vapor phase (s/m <sup>2</sup> -yr)                                                   |
| $Dywww$   | = | Unitized yearly average wet deposition from vapor phase (over water body or watershed) (s/m <sup>2</sup> -yr)                    |
| $d_z$     | = | Total water body depth (m)                                                                                                       |
| $ER$      | = | Soil enrichment ratio (unitless)                                                                                                 |
| $E_v$     | = | Average annual evapotranspiration (cm/yr)                                                                                        |
| $f_{bs}$  | = | Fraction of total water body COPC concentration in benthic sediment (unitless)                                                   |
| $Fd$      | = | Fraction of diet that is soil (unitless)                                                                                         |
| $Fw$      | = | Fraction of COPC wet deposition that adheres to plant surfaces (unitless)                                                        |
| $f_{wc}$  | = | Fraction of total water body COPC concentration in the water column (unitless)                                                   |
| $F_v$     | = | Fraction of COPC air concentration in vapor phase (unitless)                                                                     |
| $H$       | = | Henry's Law constant (atm-m <sup>3</sup> /mol)                                                                                   |
| $I$       | = | Average annual irrigation (cm/yr)                                                                                                |
| $k$       | = | Von Karman's constant (unitless)                                                                                                 |
| $K$       | = | USLE erodibility factor (ton/acre)                                                                                               |
| $k_b$     | = | Benthic burial rate constant (yr <sup>-1</sup> )                                                                                 |
| $Kd_{bs}$ | = | Bed sediment/sediment pore water partition coefficient (cm <sup>3</sup> water/g bottom sediment or L water/kg bottom sediment)   |
| $Kd_s$    | = | Soil-water partition coefficient (cm <sup>3</sup> water/g soil)                                                                  |
| $Kd_{sw}$ | = | Suspended sediment-surface water partition coefficient (L water/kg suspended sediment)                                           |
| $K_G$     | = | Gas phase transfer coefficient (m/yr)                                                                                            |
| $K_L$     | = | Liquid phase transfer coefficient (m/yr)                                                                                         |
| $K_{oc}$  | = | Soil organic carbon-water partition coefficient (mL water/g soil)                                                                |
| $K_{ow}$  | = | Octanol-water partition coefficient (mg COPC/L octanol)/(mg COPC/L octanol)—unitless                                             |
| $kp$      | = | Plant surface loss coefficient (yr <sup>-1</sup> )                                                                               |
| $ks$      | = | COPC soil loss constant due to all processes (yr <sup>-1</sup> )                                                                 |
| $kse$     | = | COPC loss constant due to soil erosion (yr <sup>-1</sup> )                                                                       |
| $ksg$     | = | COPC loss constant due to biotic and abiotic degradation (yr <sup>-1</sup> )                                                     |
| $ksl$     | = | COPC loss constant due to leaching (yr <sup>-1</sup> )                                                                           |
| $ksr$     | = | COPC loss constant due to surface runoff (yr <sup>-1</sup> )                                                                     |
| $k_{sv}$  | = | COPC loss constant due to volatilization (yr <sup>-1</sup> )                                                                     |
| $k_v$     | = | Water column volatilization rate constant (yr <sup>-1</sup> )                                                                    |
| $K_v$     | = | Overall COPC transfer rate coefficient (m/yr)                                                                                    |
| $k_{wt}$  | = | Overall total water body dissipation rate constant (yr <sup>-1</sup> )                                                           |

|              |   |                                                                                                                                                                                                                            |
|--------------|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $L_{DEP}$    | = | Total (wet and dry) particle phase and wet vapor phase COPC direct deposition load to water body (g/yr)                                                                                                                    |

**TABLE B-1-1**

**SOIL CONCENTRATION DUE TO DEPOSITION  
(SOIL EQUATIONS)**

**(Page 1 of 9)**

**Description**

The equation in this table is used to calculate the highest annual average COPC concentration in soil resulting from wet and dry deposition of particles and vapors to soil. COPCs are assumed to be incorporated only to a finite depth (the soil mixing depth,  $Z_s$ ).

The highest annual average COPC concentration in soil is assumed to occur at the end of the time period of combustion. The following uncertainty is associated with this variable:

- (1) The time period for deposition of COPCs resulting from hazardous waste combustion is assumed to be a conservative, long-term value.
- (2) Deposition to hard surfaces may result in dust residues that have negligible dilution (as a result of potential mixing with in-situ materials), in comparison to that of other residues. This uncertainty may underestimate  $C_s$ .

TABLE B-1-1

**SOIL CONCENTRATION DUE TO DEPOSITION  
(SOIL EQUATIONS)**

(Page 2 of 9)

## Equation

**Highest Annual Average Soil Concentration**

$$C_s = \frac{D_s \cdot [1 - \exp(-k_s \cdot tD)]}{k_s}$$

where:

$$D_s = \frac{100 \cdot Q}{Z_s \cdot BD} \cdot [F_v (0.31536 \cdot V_{dv} \cdot C_{yv} + D_{yvw}) + (D_{ydp} + D_{ywp}) \cdot (1 - F_v)]$$

**For mercury modeling:**

$$D_{s_{Mercury}} = \frac{100 \cdot (0.48 Q_{TotalMercury})}{Z_s \cdot BD} \cdot [F_{v_{Hg^{2+}}} (0.31536 \cdot V_{dv} \cdot C_{yv} + D_{yvw}) + (D_{ydp} + D_{ywp}) \cdot (1 - F_{v_{Hg^{2+}}})]$$

In calculating  $C_s$  for mercury compounds,  $D_s(Mercury)$  is calculated as shown above using the total mercury emission rate ( $Q$ ) measured at the stack and  $F_v$  for mercuric chloride ( $F_v = 0.85$ ). As presented below, the calculated  $D_s(Mercury)$  value is apportioned into the divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) forms based on a 98%  $Hg^{2+}$  and 2% MHg speciation split in dry land soils, and a 85%  $Hg^{2+}$  and 15% MHg speciation split in wetland soils (see Chapter 2).

**For Calculating  $C_s$  in Dry Land Soils**

$$D_s(Hg^{2+}) = 0.98 D_s(Mercury)$$

$$D_s(MHg) = 0.02 D_s(Mercury)$$

$$D_s(Hg^0) = 0.0$$

**For Calculating  $C_s$  in Wetland Soils**

$$D_s(Hg^{2+}) = 0.85 D_s(Mercury)$$

$$D_s(MHg) = 0.15 D_s(Mercury)$$

$$D_s(Hg^0) = 0.0$$

Calculate  $C_s$  for divalent and methyl mercury using the corresponding (1) fate and transport parameters for mercuric chloride (divalent mercury) and methyl mercury (provided in Appendix A-2), and (2)  $D_s(Hg^{2+})$  and  $D_s(MHg)$  as calculated above. After calculating species specific  $C_s$  values, divalent and methyl mercury should continue to be modeled throughout Appendix B equations as individual COPCs.

| Variable | Description                | Units           | Value |
|----------|----------------------------|-----------------|-------|
| $C_s$    | COPC concentration in soil | mg COPC/kg soil |       |

| $Q$         | COPC-specific emission rate | g/s               | <p><b>Varies (site-specific)</b></p> <p>This variable is COPC- and site-specific (see Chapters 2 and 3). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |             |                   |          |   |        |    |
| $Z_s$       | Soil mixing zone depth      | cm                | <p><b>1 or 20</b></p> <p><math>Z_s</math> should be computed for two depth intervals. U.S. EPA OSW recommends the following values for this variable:</p> <table><tr><td><u>Soil</u></td><td><u>Depth (cm)</u></td></tr><tr><td>Untilled</td><td>1</td></tr><tr><td>Tilled</td><td>20</td></tr></table> <p>The following uncertainty is associated with this variable:</p> <p>(1) For soluble COPCs, leaching might lead to movement to below soil depths and justify a greater mixing depth. This uncertainty may overestimate <math>C_s</math>.</p> <p>(2) Deposition to hard surfaces may result in dust residues that have negligible dilution, in comparison to that of other residues. This uncertainty may underestimate <math>C_s</math>.</p>                                                                                                                          | <u>Soil</u> | <u>Depth (cm)</u> | Untilled | 1 | Tilled | 20 |
| <u>Soil</u> | <u>Depth (cm)</u>           |                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |             |                   |          |   |        |    |
| Untilled    | 1                           |                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |             |                   |          |   |        |    |
| Tilled      | 20                          |                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |             |                   |          |   |        |    |
| $BD$        | Soil bulk density           | g/cm <sup>3</sup> | <p><b>1.5</b></p> <p>This variable is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil (Hillel 1980), as summarized in U.S. EPA (1990a). A proposed range of 0.83 to 1.84 was originally cited in Hoffman and Baes (1979). U.S. EPA (1994c) recommends a default <math>BD</math> value of 1.5 g/cm<sup>3</sup>, based on a mean value for loam soil that was obtained from Carsel, Parrish, Jones, Hansen, and Lamb (1988). The value of 1.5 g/cm<sup>3</sup> also represents the midpoint of the "relatively narrow range" for <math>BD</math> of 1.2 to 1.7 g/cm<sup>3</sup> (U.S. EPA 1993a).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended range of <math>BD</math> values may not accurately represent site-specific soil conditions.</p> |             |                   |          |   |        |    |

| Variable | Description                                       | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------|---------------------------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $F_v$    | Fraction of COPC air concentration in vapor phase | unitless             | <p style="text-align: center;"><b>0 to 1 (see Appendix A-2)</b></p> <p>This variable is COPC-specific and should be determined from the COPC tables in Appendix A-2. Values are also presented in U.S. EPA (1993), RTI (1992), and NC DEHNR (1997) based on the work of Bidleman (1988), as cited in U.S. EPA (1994c).</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) It is based on the assumption of a default <math>S_T</math> value for background plus local sources, rather than an <math>S_T</math> value for urban sources. If a specific site is located in an urban area, the use of the latter <math>S_T</math> value may be more appropriate. Specifically, the <math>S_T</math> value for urban sources is about one order of magnitude greater than that for background plus local sources, and it would result in a lower calculated <math>F_v</math> value; however, the <math>F_v</math> value is likely to be only a few percent lower.</li> <li>(2) According to Bidleman (1988), the equation used to calculate <math>F_v</math> assumes that the variable <math>c</math> (Junge constant) is constant for all chemicals. However, the value of <math>c</math> depends on the chemical (sorbate) molecular weight, the surface concentration for monolayer coverage, and the difference between the heat of desorption from the particle surface and the heat of vaporization of the liquid-phase sorbate. To the extent that site- or COPC-specific conditions may cause the value of <math>c</math> to vary, uncertainty is introduced if a constant value of <math>c</math> is used to calculate <math>F_v</math>.</li> </ol> |
| 0.31536  | Units conversion factor                           | m-g-s/cm- $\mu$ g-yr |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $V_{dv}$ | Dry deposition velocity                           | cm/s                 | <p style="text-align: center;"><b>3</b></p> <p>U.S. EPA (1994c) recommended the use of 3 cm/s for the dry deposition velocity, based on median dry deposition velocity for <math>\text{HNO}_3</math> from an unspecified U.S. EPA database of dry deposition velocities for <math>\text{HNO}_3</math>, ozone, and <math>\text{SO}_2</math>. <math>\text{HNO}_3</math> was considered the most similar to the COPCs recommended for consideration. The value should be applicable to any organic COPC with a low Henry's Law Constant.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) <math>\text{HNO}_3</math> may not adequately represent specific COPCs with high Henry's Law Constant values. Therefore, the use of a single value may under- or overestimate estimated soil concentration.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

TABLE B-1-1

**SOIL CONCENTRATION DUE TO DEPOSITION  
(SOIL EQUATIONS)**

(Page 6 of 9)

| Variable    | Description                                                | Units                    | Value                                                                                                                                                                                                                                    |

## TABLE B-1-1

### SOIL CONCENTRATION DUE TO DEPOSITION (SOIL EQUATIONS)

(Page 7 of 9)

#### REFERENCES AND DISCUSSION

Bidleman, T.F. 1988. "Atmospheric Processes." *Environmental Science and Technology*. Volume 22. Number 4. Pages 361-367.

This reference is for the statement that the equation used to calculate the fraction of air concentration in vapor phase ( $F_v$ ) assumes that the variable  $c$  (the Junge constant) is constant for all chemicals. However, this document notes that the value of  $c$  depends on the chemical (sorbate) molecular weight, the surface concentration for monolayer coverage, and the difference between the heat of desorption from the particle surface and the heat of vaporization of the liquid-phase sorbate. The following equation, presented in this document, is cited by U.S. EPA (1994c) and NC DEHNR (1997) for calculating the variable  $F_v$ :

$$F_v = 1 - \frac{c \cdot S_T}{P_L^\circ + c \cdot S_T}$$

where:

|             |   |                                                                                                                                              |
|-------------|---|----------------------------------------------------------------------------------------------------------------------------------------------|
| $F_v$       | = | Fraction of chemical air concentration in vapor phase (unitless)                                                                             |
| $c$         | = | Junge constant = 1.7 E-04 (atm-cm)                                                                                                           |
| $S_T$       | = | Whitby's average surface area of particulates = 3.5 E-06 cm <sup>2</sup> /cm <sup>3</sup> air (corresponds to background plus local sources) |
| $P_L^\circ$ | = | Liquid-phase vapor pressure of chemical (atm) (see Appendix A-2)                                                                             |

If the chemical is a solid at ambient temperatures, the solid-phase vapor pressure is converted to a liquid-phase vapor pressure as follows:

$$\ln \frac{P_L^\circ}{P_S^\circ} = \frac{\Delta S_f}{R} \cdot \frac{(T_m - T_a)}{T_a}$$

where:

|                        |   |                                                                     |
|------------------------|---|---------------------------------------------------------------------|
| $P_S^\circ$            | = | Solid-phase vapor pressure of chemical (atm) (see Appendix A-2)     |
| $\frac{\Delta S_f}{R}$ | = | Entropy of fusion over the universal gas constant = 6.79 (unitless) |
| $T_m$                  | = | Melting point of chemical (K) (see Appendix C)                      |
| $T_a$                  | = | Ambient air temperature = 298 K (25°C)                              |

Carsel, R.F., R.S. Parrish, R.L. Jones, J.L. Hansen, and R.L. Lamb. 1988. "Characterizing the Uncertainty of Pesticide Leaching in Agricultural Soils." *Journal of Contaminant Hydrology*. Vol. 2. Pages 11-24.

This reference is cited by U.S. EPA (1994b) as the source for a mean soil bulk density value of  $1.5 \text{ g/cm}^3$  for loam soil.

Hillel, D. 1980. *Fundamentals of Soil Physics*. Academic Press, Inc. New York.

This document is cited by U.S. EPA (1990a) for the statement that dry soil bulk density,  $BD$ , is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil.

Hoffman, F.O., and C.F. Baes, 1979. *A Statistical Analysis of Selected Parameters for Predicting Food Chain Transport and Internal Dose of Radionuclides*. ORNL/NOREG/TM-882.

This document presents a soil bulk density range,  $BD$ , of 0.83 to 1.84.

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This is one of the source documents for for the equation in Table B-1-1. This document also recommends the use of (1) a deposition term,  $D_s$ , and (2) COPC-specific  $F_v$  (fraction of COPC air concentration in vapor phase) values.

Research Triangle Institute (RTI). 1992. *Preliminary Soil Action Level for Superfund Sites*. Draft Interim Report. Prepared for U.S. EPA Hazardous Site Control Division, Remedial Operations Guidance Branch. Arlington, Virginia. EPA Contract 68-W1-0021. Work Assignment No. B-03, Work Assignment Manager Loren Henning. December.

This document is a reference source for COPC-specific  $F_v$  (fraction of COPC air concentration in vapor phase) values.

U.S. EPA. 1990a. *Interim Final Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Environmental Criteria and Assessment Office. Office of Research and Development. EPA 600-90-003. January.

This document is a reference source for the equation in Table B-1-1, and it recommends that (1) the time period over which deposition occurs (time period for combustion),  $tD$ , be represented by periods of 30, 60, and 100 years, and (2) undocumented values for soil mixing zone depth,  $Z_s$ , for tilled and untilled soil.

U.S. EPA. 1993. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste. Office of Research and Development. Washington, D.C. September 24.

This document is a reference for the equation in Table B-1-1. It recommends using a deposition term,  $D_s$ , and COPC-specific  $F_v$  values (fraction of COPC air concentration in vapor phase) in the  $C_s$  equation.

U.S. EPA 1994a. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. April 15.

### SOIL CONCENTRATION DUE TO DEPOSITION (SOIL EQUATIONS)

#### (Page 9 of 9)

This document is a reference for the equation in Table B-1-1; it recommends that the following be used in the  $C_s$  equation: (1) a deposition term,  $D_s$ , and (2) a default soil dry bulk density value of  $1.5 \text{ g/cm}^3$ , based on a mean value for loam soil from Carsel, Parrish, Jones, Hansen, and Lamb (1988).

U.S. EPA. 1994b. *Estimating Exposure to Dioxin-Like Compounds. Volume III: Site-Specific Assessment Procedures*. Review Draft. Office of Research and Development. Washington, D.C. June. EPA/600/6-88/005Cc.

U.S. EPA. 1994c. *Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

The value for dry deposition velocity is based on median dry deposition velocity for  $\text{HNO}_3$  from a U.S. EPA database of dry deposition velocities for  $\text{HNO}_3$  ozone, and  $\text{SO}_2$ .  $\text{HNO}_3$  was considered the most similar to the constituents covered and the value should be applicable to any organic compound having a low Henry's Law Constant. The reference document for this recommendation was not cited. This document recommends the following:

- $F_v$  values (fraction of COPC air concentration in vapor phase) that range from 0.27 to 1 for organic COPCs
- $V_{dv}$  value (dry deposition velocity) of 3 cm/s (however, no reference is provided for this recommendation)
- Default soil dry bulk density value of  $1.5 \text{ g/cm}^3$ , based on a mean for loam soil from Carsel, Parrish, Jones, Hansen, and Lamb (1988)
- $V_{dv}$  value of 3 cm/s, based on median dry deposition velocity for  $\text{HNO}_3$  from an unspecified U.S. EPA database of dry deposition velocities for  $\text{HNO}_3$ , ozone, and  $\text{SO}_2$ .  $\text{HNO}_3$  was considered the most similar to the COPCs recommended for consideration.

U.S. EPA. 1998. "Human Health Risk Assessment Protocol for Hazardous Waste Combustion Facilities." External Peer Review Draft. U.S. EPA Region 6 and U.S. EPA OSW. Volumes 1-3. EPA530-D-98-001A. July.

TABLE B-1-2

**COPC SOIL LOSS CONSTANT DUE TO ALL PROCESSES  
(SOIL EQUATIONS)**

(Page 1 of 4)

**Description**

This equation calculates the soil loss constant ( $ks$ ), which accounts for the loss of COPCs from soil by several mechanisms.

Uncertainties associated with this equation include the following:

- (1) COPC-specific values for  $ksg$  are empirically determined from field studies. No information is available regarding the application of these values to the site-specific conditions associated with affected facilities.

**Equation**

$$ks = ksg + kse + ksr + ksl + ksv$$

| Variable | Description                                              | Units            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

TABLE B-1-3

**COPC LOSS CONSTANT DUE TO SOIL EROSION  
(SOIL EQUATIONS)**

(Page 1 of 6)

**Description**

This equation calculates the constant for COPC loss resulting from erosion of soil. Consistent with U.S. EPA (1994), U.S. EPA (1994b), NC DEHNR (1997), and U.S. EPA (1998), U.S. EPA OSW recommends that the default value assumed for *kse* is zero because of contaminated soil eroding onto the site and away from the site. In site-specific cases where the permitting authority considers it appropriate to calculate a *kse*, the following equation presented in this table should be considered along with associated uncertainties. Additional discussion on the determination of *kse* can be obtained from review of the methodologies described in U.S. EPA NCEA document, *Methodology for Assessing Health Risks Associated with Multiple Exposure Pathways to Combustor Emissions* (In Press).

Uncertainties associated with this equation include:

- (1) For soluble COPCs, leaching might lead to movement below 1 cm in soils and justify a greater mixing depth. This uncertainty may overestimate *kse*.
- (2) Deposition to hard surfaces may result in dust residues that have negligible dilution (as a result of potential mixing with in-situ materials) in comparison to that of other residues. This uncertainty may underestimate *kse*.

**Equation**

$$kse = \frac{0.1 \cdot X_e \cdot SD \cdot ER}{BD \cdot Z_s} \cdot \left( \frac{Kd_s \cdot BD}{\theta_{sw} + (Kd_s \cdot BD)} \right)$$

| Variable | Description             | Units                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------|-------------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $X_e$    | Unit soil loss          | kg/m <sup>2</sup> -yr | <p style="text-align: center;"><b>Varies (calculated - Table B-2-7)</b></p> <p>This variable is site-specific and is calculated by using the equation in Table B-2-7.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) All of the equation variables are site-specific. Use of default values rather than site-specific values for any or all of these variables will result in unit soil loss (<math>X_e</math>) estimates that are under- or overestimated to some degree. Based on default values, <math>X_e</math> estimates can vary over a range of less than two orders of magnitude.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $SD$     | Sediment delivery ratio | unitless              | <p style="text-align: center;"><b>Varies (calculated - Table B-2-8)</b></p> <p>This value is site-specific and is calculated by using the equation in Table B-2-8.</p> <p>Uncertainties associated with this variable include the following:</p> <p>(1) The recommended default values for the empirical intercept coefficient, <math>a</math>, are average values that are based on studies of sediment yields from various watersheds. Therefore, those default values may not accurately represent site-specific watershed conditions. As a result, use of these default values may under- or overestimate <math>SD</math>.</p> <p>(2) The recommended default value for the empirical slope coefficient, <math>b</math>, is based on a review of sediment yields from various watersheds. This single default value may not accurately represent site-specific watershed conditions. As a result, use of this default value may under- or overestimate <math>SD</math>.</p>                                                                                                                                                                                                    |
| $ER$     | Soil enrichment ratio   | unitless              | <p style="text-align: center;"><b>Inorganics: 1<br/>Organics: 3</b></p> <p>COPC enrichment occurs because (1) lighter soil particles erode more than heavier soil particles, and (2) concentration of organic COPCs—which is a function of organic carbon content of sorbing media—is expected to be higher in eroded material than in in-situ soil (U.S. EPA 1993). In the absence of site-specific data, U.S. EPA OSW recommends a default value of 3 for organic COPCs and 1 for inorganic COPCs. This is consistent with other U.S. EPA guidance (1993), which recommends a range of 1 to 5 and a value of 3 as a "reasonable first estimate." This range has been used for organic matter, phosphorus, and other soil-bound COPCs (U.S. EPA 1993); however, no sources or references were provided for this range. <math>ER</math> is generally higher in sandy soils than in silty or loamy soils (U.S. EPA 1993).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default <math>ER</math> value may not accurately reflect site-specific conditions; therefore, <math>kse</math> may be over- or underestimated to an unknown extent.</p> |

TABLE B-1-3

**COPC LOSS CONSTANT DUE TO SOIL EROSION  
(SOIL EQUATIONS)**

(Page 3 of 6)

| Variable              | Description                      | Units              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                   |          |   |        |    |
|-----------------------|----------------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-------------------|----------|---|--------|----|
| <i>BD</i>             | Soil bulk density                | g/cm <sup>3</sup>  | <p style="text-align: center;"><b>1.5</b></p> <p>This variable is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil (Hillel 1980), as summarized in U.S. EPA (1990). A range of 0.83 to 1.84 was originally cited in Hoffman and Baes (1979). U.S. EPA (1994) recommends a default BD value of 1.5 g/cm<sup>3</sup>, based on a mean value for loam soil that was taken from Carsel, Parrish, Jones, Hansen, and Lamb (1988). The value of 1.5 g/cm<sup>3</sup> also represents the midpoint of the "relatively narrow range" for <i>BD</i> of 1.2 to 1.7 g/cm<sup>3</sup> (U.S. EPA 1993).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended range of soil dry bulk density values may not accurately represent site-specific soil conditions.</p> |             |                   |          |   |        |    |
| <i>Z<sub>s</sub></i>  | Soil mixing zone depth           | cm                 | <p style="text-align: center;"><b>1 or 20</b></p> <p>U.S. EPA OSW recommends the following values for this variable:</p> <table><tr><td><u>Soil</u></td><td><u>Depth (cm)</u></td></tr><tr><td>Untilled</td><td>1</td></tr><tr><td>Tilled</td><td>20</td></tr></table> <p>The following uncertainty is associated with this variable:</p> <p>(1) For soluble COPCs, leaching might lead to movement to below 1 cm in soils and justify a greater mixing depth. This uncertainty may overestimate <i>k<sub>se</sub></i>.</p> <p>(2) Deposition to hard surfaces may result in dust residues that have negligible dilution (as a result of potential mixing with in-situ materials), in comparison to that of other residues. This uncertainty may underestimate <i>k<sub>se</sub></i>.</p>                                                                                      | <u>Soil</u> | <u>Depth (cm)</u> | Untilled | 1 | Tilled | 20 |
| <u>Soil</u>           | <u>Depth (cm)</u>                |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |             |                   |          |   |        |    |
| Untilled              | 1                                |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |             |                   |          |   |        |    |
| Tilled                | 20                               |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |             |                   |          |   |        |    |
| <i>Kd<sub>s</sub></i> | Soil-water partition coefficient | cm <sup>3</sup> /g | <p style="text-align: center;"><b>Varies (see Appendix A-2)</b></p> <p>This variable is COPC-specific and should be determined from the COPC tables in Appendix A-2.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Uncertainties associated with this parameter will be limited if <i>Kd<sub>s</sub></i> values are determined as described in Appendix A-2.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |             |                   |          |   |        |    |

#### REFERENCES AND DISCUSSION

Carsel, R.F., R.S. Parish, R.L. Jones, J.L. Hansen, and R.L. Lamb. 1988. "Characterizing the Uncertainty of Pesticide Leaching in Agricultural Soils." *Journal of Contaminant Hydrology*. Vol. 2. Pages 11-24.

This document is cited by U.S. EPA (1994) as the source for a mean soil bulk density,  $BD$ , value of 1.5 g/cm<sup>3</sup> for loam soil.

Hillel, D. 1980. *Fundamentals of Soil Physics*. Academic Press, Inc. New York.

This document is cited by U.S. EPA (1990) for the statement that dry soil bulk density,  $BD$ , is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil.

Hoffman, F.O., and C.F. Baes. 1979. *A Statistical Analysis of Selected Parameters for Predicting Food Chain Transport and Internal Dose of Radionuclides*. ORNL/NUREG/TM-882.

This document presents a soil bulk density,  $BD$ , range of 0.83 to 1.84.

NC DEHNR. 1997. *Draft NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

U.S. EPA. 1990. *Interim Final Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Environmental Criteria and Assessment Office. Office of Research and Development. EPA 600-90-003. January.

This document presents a range of values for soil mixing zone depth,  $Z_s$ , for tilled and untilled soil. The basis or source of these values is not identified.

U.S. EPA. 1993. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November 1993.

This document is the source of a range of COPC enrichment ratio,  $ER$ , values. The recommended range, 1 to 5, has been used for organic matter, phosphorous, and other soil-bound COPCs. This document recommends a value of 3 as a "reasonable first estimate," and states that COPC enrichment occurs because lighter soil particles erode more than heavier soil particles. Lighter soil particles have higher ratios of surface area to volume and are higher in organic matter content. Therefore, concentration of organic COPCs, which is a function of the organic carbon content of sorbing media, is expected to be higher in eroded material than in in-situ soil.

This document is also a source of the following:

- A "relatively narrow range" for soil dry bulk density,  $BD$ , of 1.2 to 1.7 g/cm<sup>3</sup>
- COPC-specific (inorganic COPCs only)  $Kd_s$  values used to develop a proposed range (2 to 280,000 mL/g) of  $Kd_s$  values
- A range of soil volumetric water content ( $\theta_{sw}$ ) values of 0.1 mL/cm<sup>3</sup> (very sandy soils) to 0.3 mL/cm<sup>3</sup> (heavy loam/clay soils) (however, no source or reference is provided for this range)

TABLE B-1-4

**COPC LOSS CONSTANT DUE TO RUNOFF  
(SOIL EQUATIONS)**

(Page 1 of 5)

**Description**

This equation calculates the constant for COPC loss resulting from runoff of soil. Uncertainties associated with this equation include the following:

- (1) For soluble COPCs, leaching might lead to movement to below 1 cm in soils and resulting in a greater mixing depth. This uncertainty may overestimate *ksr*.
- (2) Deposition to hard surfaces may result in dust residues that have negligible dilution, in comparison to that of other residues. This uncertainty may underestimate *ksr*.

**Equation**

$$ksr = \frac{RO}{\theta_{sw} \cdot Z_s} \cdot \left( \frac{1}{1 + (Kd_s \cdot BD / \theta_{sw})} \right)$$

| <i>ksr</i> | COPC loss constant due to surface runoff | yr <sup>-1</sup> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>RO</i>  | Average annual surface runoff            | cm/yr            | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific. According to U.S. EPA (1993; 1994b) and NC DEHNR (1997), average annual surface runoff can be estimated by using the <i>Water Atlas of the United States</i> (Geraghty, Miller, Van der Leeden, and Troise 1973). According to NC DEHNR, (1997), estimates can also be made by using more detailed, site-specific procedures for estimating the amount of surface runoff, such as those based on the U.S. Soil Conservation Service curve number equation (CNE). U.S. EPA (1985) is cited as an example of such a procedure.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) To the extent that site-specific or local average annual surface runoff information is not available, default or estimated values may not accurately represent site-specific or local conditions. As a result, <i>ksl</i> may be under- or overestimated to an unknown degree.</li> </ol> |

#### REFERENCES AND DISCUSSION

Carsel, R.F., R.S. Parrish, R.L. Jones, J.L. Hansen, and R.L. Lamb. 1988. "Characterizing the Uncertainty of Pesticide Leaching in Agricultural Soils." *Journal of Contaminant Hydrology*. Vol. 2. Pages 11-24.

This document is cited by U.S. EPA (1994) as the source of a mean soil bulk density,  $BD$ , value of  $1.5 \text{ g/cm}^3$  for loam soil.

Geraghty, J.J., D.W. Miller, F. Van der Leeden, and F.L. Troise. 1973. *Water Atlas of the United States*. Water Information Center, Port Washington, New York.

This document is cited by U.S. EPA (1993), U.S. EPA (1994c), and NC DEHNR (1997) as a reference to calculate average annual runoff,  $R$ . This reference provides maps with isolines of annual average surface water runoff, which is defined as all flow contributions to surface water bodies, including direct runoff, shallow interflow, and ground water recharge. Because these values are total contributions, and not only surface runoff, U.S. EPA (1994c) recommends that they be reduced by 50 percent to estimate surface runoff.

Hillel, D. 1980. *Fundamentals of Soil Physics*. Academic Press, Inc. New York.

This document is cited by U.S. EPA (1990) for the statement that dry soil bulk density,  $BD$ , is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil.

Hoffman, F.O., and C.F. Baes. 1979. *A Statistical Analysis of Selected Parameters for Predicting Food Chain Transport and Internal Dose of Radionuclides*. ORNL/NUREG/TM-882.

This document presents a soil bulk density,  $BD$ , range of 0.83 to 1.84.

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is one of the source documents that cites the use of the equation in Table B-1-4; however, this document is not the original source of this equation (this source is unknown). This document also recommends the following:

- Estimation of annual current runoff,  $RO$  (cm/yr), by using the *Water Atlas of the United States* (Geraghty, Miller, Van der Leeden, and Troise 1973) or site-specific procedures, such as using the U.S. Soil Conservation Service curve number equation (CNE) (U.S. EPA [1985]) is cited as an example of the use of the CNE
- Default value of  $0.2 \text{ mL/cm}^3$  for soil volumetric water content ( $\theta_{sw}$ )
- Range (2 to 280,000 mL/g) of  $Kd_s$  values for inorganic COPCs (the original source of the values is not identified)

U.S. EPA. 1985. *Water Quality Assessment: A Screening Procedure for Toxic and Conventional Pollutants in Surface and Ground Water—Part I (Revised. 1985)*. Environmental Research Laboratory. Athens, Georgia. EPA/600/6-85/002a. September.

This document is cited by NC DEHNR (1997) as an example of the use of the U.S. Soil Conservation Service CNE to estimate site-specific surface runoff.

U.S. EPA. 1990. *Interim Final Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Environmental Criteria and Assessment Office. Office of Research and Development. EPA 600-90-003. January.

## TABLE B-1-4

### COPC LOSS CONSTANT DUE TO RUNOFF (SOIL EQUATIONS)

(Page 5 of 5)

This document presents the statement that dry soil bulk density,  $BD$ , is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil.

U.S. EPA. 1993. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November.

This document recommends the following:

- A “relatively narrow range” for soil dry bulk density,  $BD$ , of 1.2 to 1.7 g./cm<sup>3</sup>
- A range of soil volumetric water content,  $\theta_{sw}$ , values of 0.1 (very sandy soils) to 0.3 (heavy loam/clay soils) (the original source of, or reference for, these values is not identified)
- A range (2 to 280,000 mL/g) of  $Kd_s$  values for inorganic COPCs
- Use of the *Water Atlas of the United States* (Geraghty, Miller, Van der Leeden, and Troise 1973) to calculate average annual runoff

U.S. EPA. 1994a. *Estimating Exposure to Dioxin-Like Compounds. Volume III: Site-specific Assessment Procedures*. External Review Draft. Office of Research and Development. Washington, D.C. EPA/600/6-88/005Cc. June.

This document presents a range of values for soil mixing zone depth,  $Z_s$ , for tilled and untilled soil as cited in U.S. EPA (1993).

U.S. EPA. 1994b. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes*. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities. Offices of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document recommends the following:

- Estimation of average annual runoff,  $RO$ , by using the *Water Atlas of the United States* (Geraghty, Miller, Van der Leeden, and Troise 1973)
- Default soil dry bulk density,  $BD$ , value of 1.5 g/cm<sup>3</sup>, based on the mean for loam soil that is taken from Carsel, Parrish, Jones, Hansen, and Lamb (1988)
- Default soil volumetric water content,  $\theta_{sw}$ , value of 0.2 mL/cm<sup>3</sup>, based on U.S. EPA (1993)

| <p>This equation calculates the constant for COPC loss resulting from leaching of soil. Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) For soluble COPCs, leaching might lead to movement to below 1 or 20 cm in soils; resulting in a greater mixing depth. This uncertainty may overestimate <i>ksl</i>.</li> <li>(2) Deposition to hard surfaces may result in dust residues that have negligible dilution (as a result of potential mixing with in-situ materials), in comparison to that of other residues. This uncertainty may underestimate <i>ksl</i>.</li> <li>(3) The original source of this equation has not been identified. U.S. EPA (1993) presents the equation as shown here. U.S. EPA (1994) and NC DEHNR (1997) replaced the numerator as shown with “<i>q</i>”, defined as average annual recharge (cm/yr).</li> </ol> |                                    |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|----------------------|-----------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>I</i>             | Average annual irrigation         | cm/yr | <p style="text-align: center;"><b>0 to 100 (site-specific)</b></p> <p>This variable is site-specific. This range is based on information, presented in U.S. EPA (1990), representing data for 69 selected cities (Baes, Sharp, Sjoeren, and Shor 1984). The 69 selected cities are not identified; however, they appear to be located throughout the continental United States.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) To the extent that site-specific or local average annual irrigation information is not available, default values (generally based on the closest comparable location) may not accurately reflect site-specific conditions. As a result, <i>ksl</i> may be under- or overestimated to an unknown degree.</p>                                                                                                                                                     |
| <i>RO</i>            | Average annual surface runoff     | cm/yr | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific. According to U.S. EPA (1993; 1994) and NC DEHNR (1997), average annual surface runoff can be estimated by using the Water Atlas of the United States (Geraghty, Miller, Van der Leeden, and Troise 1973). Also according to NC DEHNR (1997), this estimate can also be made by using more detailed, site-specific procedures, such as those based on the U.S. Soil Conservation Service CNE. U.S. EPA (1985) is cited as an example of such a procedure.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) To the extent that site-specific or local average annual surface runoff information is not available, default or estimated values may not accurately represent site-specific or local conditions. As a result, <i>ksl</i> may be under- or overestimated to an unknown degree.</p> |
| <i>E<sub>v</sub></i> | Average annual evapotranspiration | cm/yr | <p style="text-align: center;"><b>35 to 100 (site-specific)</b></p> <p>This variable is site-specific. | Variable      | Description                   | Units              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |             |                   |          |   |        |    |
|---------------|-------------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-------------------|----------|---|--------|----|
| $\theta_{sw}$ | Soil volumetric water content | mL/cm <sup>3</sup> | <p style="text-align: center;"><b>0.2</b></p> <p>This variable depends on the available water and on soil structure. <math>\theta_{sw}</math> can be estimated as the midpoint between a soil's field capacity and wilting point, if a representative watershed soil can be identified. However, U.S. EPA OSW recommends the use of 0.2 mL/cm<sup>3</sup> as a default value. This value is the midpoint of the range of 0.1 (very sandy soils) to 0.3 (heavy loam/clay soils) recommended by U.S. EPA (1993) (no source or reference is provided for this range) and is consistent with U.S. EPA (1994).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default <math>\theta_{sw}</math> values may not accurately reflect site-specific or local conditions; therefore, <i>ksl</i> may be under- or overestimated to a small extent, based on the limited range of values.</p> |             |                   |          |   |        |    |
| $Z_s$         | Soil mixing zone depth        | cm                 | <p style="text-align: center;"><b>1 or 20</b></p> <p>U.S. EPA OSW recommends the following values for this variable:</p> <table><tr><td><u>Soil</u></td><td><u>Depth (cm)</u></td></tr><tr><td>Untilled</td><td>1</td></tr><tr><td>Tilled</td><td>20</td></tr></table> <p>Uncertainties associated with this variable include the following:</p> <p>(1) For soluble COPCs, leaching might lead to movement to below 1 or 20 cm in soils; resulting in a greater mixing depth. This uncertainty may overestimate <i>ksl</i>.</p> <p>(2) Deposition to hard surfaces may result in dust residues that have negligible dilution, in comparison to that of other residues. This uncertainty may underestimate <i>ksl</i>.</p>                                                                                                                                                                                           | <u>Soil</u> | <u>Depth (cm)</u> | Untilled | 1 | Tilled | 20 |
| <u>Soil</u>   | <u>Depth (cm)</u>             |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                   |          |   |        |    |
| Untilled      | 1                             |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                   |          |   |        |    |
| Tilled        | 20                            |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                   |          |   |        |    |

TABLE B-1-5

**COPC LOSS CONSTANT DUE TO LEACHING  
(SOIL EQUATIONS)**

| Variable | Description                      | Units                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|----------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $BD$     | Soil bulk density                | $\text{g/cm}^3$        | <p style="text-align: center;"><b>1.5</b></p> <p>This variable is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil (Hillel 1980), as summarized in U.S. EPA (1990). A range of 0.83 to 1.84 was originally cited in Hoffman and Baes (1979). U.S. EPA (1994) recommended a default soil bulk density value of 1.5 <math>\text{g/cm}^3</math>, based on a mean value for loam soil from Carsel, Parrish, Jones, Hansen, and Lamb (1988). The value of 1.5 <math>\text{g/cm}^3</math> also represents the midpoint of the “relatively narrow range” for <math>BD</math> of 1.2 to 1.7 <math>\text{g/cm}^3</math> (U.S. EPA 1993).</p> <p>The following uncertainties is associated with this variable:</p> <p>(1) The recommended range of soil dry bulk density values may not accurately represent site-specific soil conditions.</p> |
| $Kd_s$   | Soil-water partition coefficient | $\text{cm}^3/\text{g}$ | <p style="text-align: center;"><b>Varies (see Appendix A-2)</b></p> <p>This variable is COPC-specific and should be determined from the COPC tables in Appendix A-2.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Uncertainties associated with this parameter will be limited if <math>Kd_s</math> values are calculated as described in Appendix A-2.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### COPC LOSS CONSTANT DUE TO LEACHING (SOIL EQUATIONS)

(Page 5 of 6)

#### REFERENCES AND DISCUSSION

Baes, C.F., R.D. Sharp, A.L. Sjoreen and R.W. Shor. 1984. "A Review and Analysis of Parameters for Assessing Transport of Environmentally Released Radionuclides through Agriculture." Prepared for the U.S. Department of Energy under Contract No. DEAC05-84OR21400.

For the continental United States, as cited in U.S. EPA (1990), this document is the source of a series of maps showing: (1) average annual precipitation ( $P$ ); (2) average annual irrigation ( $I$ ); and (3) average annual evapotranspiration isolines.

Carsel, R.F., R.S. Parrish, R.L. Jones, J.L. Hansen, and R.L. Lamb. 1988. "Characterizing the Uncertainty of Pesticide Leaching in Agricultural Soils." *Journal of Contaminant Hydrology*. Vol. 2. Pages 11-24.

This document is cited by U.S. EPA (1994b) as the source for a mean soil bulk density value of 1.5 g/cm<sup>3</sup> for loam soil.

Geraghty, J.J., D.W. Miller, F. Van der Leeden, and F.L. Troise. 1973. *Water Atlas of the United States*. Water Information Center, Port Washington, New York.

This document is cited by U.S. EPA (1993), U.S. EPA (1994), and NC DEHNR (1997) as a reference for calculating average annual runoff,  $RO$ . This document provides maps with isolines of annual average surface runoff, which is defined as all flow contributions to surface water bodies, including direct runoff, shallow interflow, and ground water recharge. Because these volumes are total contributions—and not only surface runoff—U.S. EPA (1994) notes that they need to be reduced by 50 percent to estimate average annual surface runoff.

This document presents a soil bulk density,  $BD$ , range of 0.83 to 1.84. U.S. EPA has not completed its review of this document.

Hillel, D. 1980. *Fundamentals of Soil Physics*. Academic Press, Inc. New York, New York.

This document is cited by U.S. EPA (1990) for the statement that dry soil bulk density,  $BD$ , is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil.

Hoffman, F.O., and C.F. Baes. 1979. *A Statistical Analysis of Selected Parameters for Predicting Food Chain Transport and Internal Dose of Radionuclides*. ORNL/NUREG/TM-882.

This document presents a soil bulk density,  $BD$ , range of 0.83 to 1.84.

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is one of the source documents that cites the use of the equation in Table B-1-5; however, the document is not the original source of this equation. This document also recommends the following:

- Estimation of average annual surface runoff,  $RO$  (cm/yr), by using the *Water Atlas of the United States* (Geraghty, Miller, Van der Leeden, and Troise 1973) or site-specific procedures, such as using the U.S. Soil Conservation Service CNE; U.S. EPA 1985 is cited as an example of the use of the CNE.

## TABLE B-1-5

### COPC LOSS CONSTANT DUE TO LEACHING (SOIL EQUATIONS)

(Page 6 of 6)

- A default value of 0.2 mL/cm<sup>3</sup> for soil volumetric water content,  $\theta_{sw}$ .
- A range (2 to 280,000 mL/g) of  $Kd_s$  values for inorganic COPCs; the original source of these values is not identified.

U.S. Bureau of the Census. 1987. *Statistical Abstract of the United States: 1987*. 107th edition. Washington, D.C.

This document is a source of average annual precipitation ( $P$ ) information for 69 selected cites, as cited in U.S. EPA (1990); these 69 cities are not identified.

U.S. EPA. 1985. *Water Quality Assessment: A Screening Procedure for Toxic and Conventional Pollutants in Surface and Groundwater*. Part I (Revised 1985). Environmental Research Laboratory. Athens, Georgia. EPA/600/6-85/002a. September.

This document is cited by NC DEHNR (1997) as an example of the use of the U.S. Soil Conservation Service CNE to estimate site-specific average annual surface runoff.

U.S. EPA. 1990. *Interim Final Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Environmental Criteria and Assessment Office. Office of Research and Development. EPA 600-90-003. January.

This document presents ranges of (1) average annual precipitation, (2) average annual irrigation, and (3) average annual evapotranspiration. This document identifies Baes, Sharp, Sjoreen, and Shor (1984) and U.S. Bureau of the Census (1987) as the original sources of this information.

U.S. EPA. 1993. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November.

This document is one of the reference sources for the equation in Table B-1-5; this document also recommends the following:

- A range of soil volumetric water content,  $\theta_{sw}$ , values of 0.1 (very sandy soils) to 0.3 (heavy loam/clay soils); the original source or reference for these values is not identified.
- A range (2 to 280,000 mL/g) of  $Kd_s$  values for inorganic COPCs
- A “relatively narrow range” for soil dry bulk density,  $BD$ , of 1.2 to 1.7 g/cm<sup>3</sup>

This document is one of the reference source documents for equation in Table B-1-5. The original source of this equation is not identified.

U.S. EPA. 1994. *Review Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document recommends (1) a default soil volumetric water content,  $\theta_{sw}$ , value of 0.2 mL/cm<sup>3</sup>, based on U.S. EPA (1993), and (2) a default soil bulk density,  $BD$ , value of 1.5 g/cm<sup>3</sup>, based on a mean value for loam soil from Carsel, Parrish, Jones, Hansen, and Lamb (1988).

| <p>This equation calculates the COPC loss constant from soil due to volatilization, and was obtained from <i>Methodology for Assessing Health Risks Associated with Multiple Exposure Pathways to Combustor Emissions</i> (U.S. EPA In Press). The soil loss constant due to volatilization (<math>k_{sv}</math>) is based on gas equilibrium coefficients and gas phase mass transfer. The first order decay constant, <math>k_{sv}</math>, is obtained by adapting the Hwang and Falco equation for soil vapor phase diffusion (Hwang and Falco 1986).</p> <p>Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) For soluble COPCs, leaching might lead to movement to below 1 centimeter in untilled soils, resulting in a greater mixing depth. This uncertainty may overestimate <math>k_{sv}</math>.</li> <li>(2) Deposition to hard surfaces may result in dust residues that have negligible dilution (as a result of potential mixing with <i>in situ</i> materials) in comparison to that of other residues. This uncertainty may underestimate <math>k_{sv}</math>.</li> </ol> |                                          |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Equation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                          |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|----------|----------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $BD$     | Soil bulk density          | $\text{g/cm}^3$        | <p style="text-align: center;"><b>1.5</b></p> <p>This variable is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil (Hillel 1980; Miller and Gardiner 1998), as summarized in U.S. EPA (1990). A range of 0.83 to 1.84 was originally cited in Hoffman and Baes (1979). U.S. EPA (1994) recommended a default soil bulk density value of 1.5 <math>\text{g/cm}^3</math>, based on a mean value for loam soil from Carsel, Parrish, Jones, Hansen, and Lamb (1988). The value of 1.5 <math>\text{g/cm}^3</math> also represents the midpoint of the “relatively narrow range” for <math>BD</math> of 1.2 to 1.7 <math>\text{g/cm}^3</math> (U.S. EPA 1993).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended range of soil bulk density values may not accurately represent site-specific soil conditions.</p> |
| $\rho_s$ | Solids particle density    | $\text{g/cm}^3$        | <p style="text-align: center;"><b>2.7</b></p> <p>U.S. EPA OSW recommends the use of this value, based on Blake and Hartage (1996) and Hillel (1980).</p> <p>The solids particle density will vary with location and soil type.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| $D_a$    | Diffusivity of COPC in air | $\text{cm}^2/\text{s}$ | <p style="text-align: center;"><b>Varies (see Appendix A-2)</b></p> <p>This value is COPC-specific and should be determined from the COPC tables presented in Appendix A-2.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default <math>D_a</math> values may not accurately represent the behavior of COPCs under site-specific conditions. However, the degree of uncertainty is expected to be minimal.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Variable      | Definition                    | Units              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-------------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\theta_{sw}$ | Soil volumetric water content | mL/cm <sup>3</sup> | <p style="text-align: center;"><b>0.2</b></p> <p>This variable depends on the available water and on soil structure. <math>\theta_{sw}</math> can be estimated as the midpoint between a soil's field capacity and wilting point, if a representative watershed soil can be identified. However, U.S. EPA OSW recommends the use of 0.2 mL/cm<sup>3</sup> as a default value. This value is the midpoint of the range of 0.1 (very sandy soils) to 0.3 (heavy loam/clay soils) recommended by U.S. EPA (1993) (no source or reference is provided for this range) and is consistent with U.S. EPA (1994).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default <math>\theta_{sw}</math> values may not accurately reflect site-specific or local conditions; therefore, <math>ksl</math> may be under- or overestimated to a small extent, based on the limited range of values.</p> |

This document is one of the source documents that cites the use of the equation in Table B-1-6; however, the original source of this equation is not identified. This document also recommends the following:

- A range of COPC-specific Henry's Law Constant (atm-m<sup>3</sup>/mol) values
- A range (2 to 280,000 mL/g) of *K<sub>d</sub>* values for inorganic COPCs; however, the sources of these values are not identified.
- A range (9.2 E-06 to 2.8 E-01 cm<sup>2</sup>/sec) of values for diffusivity of COPCs in air; however, the sources of these values are not identified.

U. S. EPA. 1990. *Interim Final Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Environmental Criteria and Assessment Office. Office of Research and Development. EPA 600-90-003. January.

This document recommends the following:

- A default ambient air temperature of 298 K

## TABLE B-1-6

### COPC LOSS CONSTANT DUE TO VOLATILIZATION (SOIL EQUATIONS)

(Page 6 of 6)

- An average annual wind speed of 3.9 m/s; however, no source or reference for this value is identified.

U.S. EPA. 1993. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November.

This document is one of the reference source documents for the equation in Table B-1-6; however, the original reference for this equation is not identified.

This document also presents the following:

- COPC-specific  $K_d$  values that were used to establish a range (2 to 280,000 mL/g) of  $K_d$  values for inorganic COPCs
- a “relatively narrow range” for soil dry bulk density,  $BD$ , of 1.2 to 1.7 g/cm<sup>3</sup>

U.S. EPA. 1994. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Waste. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document recommends a default soil density,  $BD$ , value of 1.5 g/cm<sup>3</sup>, based on a mean value for loam soil that is taken from Carsel, Parrish, Jones, Hansen, and Lamb (1988).

| Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                             |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>This equation calculates the total average water body load from wet and dry vapor and particle deposition, runoff, and erosion loads.</p> <p>The limitations and uncertainties incorporated by using this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The greatest uncertainties are associated with the site-specific variables in Tables B-2-2, B-2-3, B-2-4, B-2-5, and B-2-6 (used to estimate values for the variables in the below equation for <math>L_T</math>). These variables include <math>Q</math>, <math>Dywwv</math>, <math>Dytwp</math>, <math>A_w</math>, <math>Cyww</math>, <math>A_r</math>, <math>A_L</math>, <math>Cs</math>, and <math>X_e</math>. Values for many of these variables are estimated through the use of mathematical models and the uncertainties associated with values for these variables may be significant in some cases.</li> <li>(2) Uncertainties associated with the remaining variables in Tables B-2-2, B-2-3, B-2-4, B-2-5, and B-2-6 are expected to be less significant, primarily because of the narrow ranges of probable values for these variables or because values for these variables (such as <math>Kd_s</math>) were estimated by using well-established estimation methods.</li> </ol> |                                                                                             |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Equation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                             |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

TABLE B-2-2

**DEPOSITION TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 3)

**Description**

This equation calculates the average load to the water body from direct deposition of wet and dry particles and wet vapors onto the surface of the water body.

Uncertainties associated with this equation include the following:

- (1) Most of the uncertainties associated with the variables in this equation, specifically those associated with  $Q$ ,  $Dywwv$ ,  $Dytwp$ , and  $A_w$ .
- (2) It is calculated on the basis of the assumption of a default  $S_T$  value for background plus local sources, rather than an  $S_T$  value for urban sources. If a specific site is located in an urban area, the use of the latter  $S_T$  value may be more appropriate. Specifically, the  $S_T$  value for urban sources is about one order of magnitude greater than that for background plus local sources and would result in a lower calculated  $F_v$  value; however, the  $F_v$  value is likely to be only a few percent lower.

**Equation**

$$L_{DEP} = Q \cdot [F_v \cdot Dywwv + (1 - F_v) \cdot Dytwp] \cdot A_w$$

**For mercury modeling:**

$$L_{DEP_{Mercury}} = 0.48Q_{TotalMercury} \cdot [F_{v_{Hg^{2+}}} \cdot Dywwv + (1 - F_{v_{Hg^{2+}}}) \cdot Dytwp] \cdot A_w$$

In calculating  $L_{DEP}$  for mercury compounds,  $L_{DEP}(Mercury)$  is calculated as shown above using the total mercury emission rate ( $Q$ ) measured at the stack and  $F_v$  for mercuric chloride ( $F_v = 0.85$ ). As presented below, the calculated  $L_{DEP}(Mercury)$  value is apportioned into the divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) forms based on a 85%  $Hg^{2+}$  and 15% MHg speciation split in the water body (see Chapter 2).

$$\begin{aligned} L_{DEP}(Hg^{2+}) &= 0.85 L_{DEP} Mercury \\ L_{DEP}(MHg) &= 0.15 L_{DEP} Mercury \end{aligned}$$

After calculating species specific  $L_{DEP}$  values, divalent and methyl mercury should continue to be modeled throughout Appendix B equations as individual COPCs.

## TABLE B-2-2

### DEPOSITION TO WATER BODY (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 3 of 3)

#### REFERENCES AND DISCUSSION

Bidleman, T.F. 1988. "Atmospheric Processes." *Environmental Science and Technology*. Volume 22. Number 4. Pages 361-367.

Junge, C.E. 1977. *Fate of Pollutants in Air and Water Environments, Part I*. Suffet, I.H., Ed. Wiley. New York. Pages 7-26.

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is a reference source for the equation in B-2-2. This document also recommends by using the equations in Bidleman (1988) to calculate  $F_v$  values for all organics other than dioxins (PCDD/PCDFs). However, the document does not present a recommendation for dioxins. Finally, this document states that metals are generally entirely in the particulate phase ( $F_v = 0$ ) except for mercury, which is assumed to be entirely in the vapor phase. The document does not state whether  $F_v$  for mercury should be calculated by using the equations in Bidleman (1988).

U.S. EPA. 1994. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document is a reference source for the equation in Table B-2-2. This document also presents values for organic COPCs that range from 0.27 to 1.  $F_v$  values for organics other than PCDD/PCDFs are calculated by using the equations presented in Bidleman (1988). The  $F_v$  value for PCDD/PCDFs is assumed to be 0.27, based on U.S. EPA (no date). Finally, this document presents  $F_v$  values for inorganic COPCs equal to 0, based on the assumption that these COPCs are nonvolatile and assumed to be 100 percent in the particulate phase and 0 percent in the vapor phase.

TABLE B-2-3

**DIFFUSION LOAD TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 4)

**Description**

This equation calculates the load to the water body due to dry vapor diffusion. Uncertainties associated with this equation include the following:

- (1) Most of the uncertainties associated with the variables in this equation, specifically those associated with  $K_v$ ,  $Q$ ,  $C_{yw}$ , and  $A_w$ , are site-specific.
- (2) This equation assumes a default  $S_T$  value for background plus local sources, rather than an  $S_T$  value for urban sources. If a specific site is located in an urban area, the use of the latter  $S_T$  value may be more appropriate. Specifically, the  $S_T$  value for urban sources is about one order of magnitude greater than that for background plus local sources and would result in a lower calculated  $F_v$  value; however, the  $F_v$  value is likely to be only a few percent lower.

**Equation**

$$L_{Dif} = \frac{K_v \cdot Q \cdot F_v \cdot C_{yw} \cdot A_w \cdot 1.0 \times 10^{-6}}{\frac{H}{R \cdot T_{wk}}}$$

**For mercury modeling:**

$$L_{Dif_{Mercury}} = \frac{K_{v_{Hg^{2+}}} \cdot 0.48 Q_{TotalMercury} \cdot F_{v_{Hg^{2+}}} \cdot C_{yw} \cdot A_w \cdot 1.0 \times 10^{-6}}{\frac{H_{Hg^{2+}}}{R \cdot T_{wk}}}$$

In calculating  $L_{Dif}$  for mercury compounds,  $L_{Dif}(Mercury)$  is calculated as shown above using the total mercury emission rate ( $Q$ ) measured at the stack and  $F_v$  for mercuric chloride ( $F_v = 0.85$ ). As presented below, the calculated  $L_{Dif}(Mercury)$  value is apportioned into the divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) forms based on a 85%  $Hg^{2+}$  and 15% MHg speciation split in the water body (see Chapter 2).

$$\begin{aligned} L_{Dif}(Hg^{2+}) &= 0.85 L_{Dif}Mercury \\ L_{Dif}(MHg) &= 0.15 L_{Dif}Mercury \end{aligned}$$

After calculating species specific  $L_{Dif}$  values, divalent and methyl mercury should continue to be modeled throughout Appendix B equations as individual COPCs.

| $L_{Dif}$ | Dry vapor phase diffusion load to water body                                 | g/yr                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| $K_v$     | Overall transfer rate coefficient                                            | m/yr                  | <p style="text-align: center;"><b>Varies (calculated - Table 2-13)</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-13.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $Q$       | COPC-specific emission rate                                                  | g/s                   | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is COPC- and site-specific (see Chapters 2 and 3). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $F_v$     | Fraction of COPC air concentration in vapor phase                            | unitless              | <p style="text-align: center;"><b>0 to 1 (see Appendix A-2)</b></p> <p>This variable is COPC-specific and should be determined from the COPC tables in Appendix A-2.</p> <p>Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) This equation assumes a default <math>S_T</math> value for background plus local sources, rather than an <math>S_T</math> value for urban sources. If a specific site is located in an urban area, the use of the latter <math>S_T</math> value may be more appropriate. Specifically, the <math>S_T</math> value for urban sources is about one order of magnitude greater than that for background plus local sources and would result in a lower calculated <math>F_v</math> value; however, the <math>F_v</math> value is likely to be only a few percent lower.</li> <li>(2) According to Bidleman (1988), the equation used to calculate <math>F_v</math> assumes that the variable <math>c</math> is constant for all chemicals; however, the value of <math>c</math> depends on the chemical (sorbate) molecular weight, the surface concentration for monolayer coverage, and the difference between the heat of desorption from the particle surface and the heat of vaporization of the liquid-phase sorbate. To the extent that site- or COPC-specific conditions may cause the value of <math>c</math> to vary, uncertainty is introduced if a constant value of <math>c</math> is used to calculate <math>F_v</math>.</li> </ol> |
| $C_{yww}$ | Unitized yearly average air concentration from vapor phase (over water body) | $\mu\text{g-s/g-m}^3$ | <p style="text-align: center;"><b>Varies (modeled)</b></p> <p>This variable is COPC- and site-specific, and is determined for each water body by air dispersion modeling (see Chapter 3). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

TABLE B-2-3

**DIFFUSION LOAD TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

## TABLE B-2-3

### DIFFUSION LOAD TO WATER BODY (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 4 of 4)

#### REFERENCES AND DISCUSSION

Bidleman, T.F. 1988. "Atmospheric Processes." *Environmental Science and Technology*. Volume 22. Number 4. Pages 361-367.

NC DEHNR. 1997. NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units. January.

This document is a reference source for the equation in Table B-2-3. This document also recommends using the equations in Bidleman (1988) to calculate  $F_v$  values for all organics other than dioxins (PCDD/PCDFs).

U.S. EPA. 1993. *Addendum to Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Solid Waste and Office Research and Development. Washington, D.C. November 10.

This document recommends a range (10°C to 30°C, 283 K to 303 K) for water body temperature,  $T_{wk}$ . No source was identified for this range.

U.S. EPA 1994. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document is cited as the reference source for  $T_{wk}$ , water body temperature (298 K); however, no references or sources are identified for this value. This document is a reference source for the equation in Table B-2-2.

TABLE B-2-4

**IMPERVIOUS RUNOFF LOAD TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 3)

**Description**

This equation calculates the average runoff load to the water body from impervious surfaces in the watershed from which runoff is conveyed directly to the water body.

Uncertainties associated with this equation include the following:

- (1) Most of the uncertainties associated with the variables in this equation, specifically those associated with  $Q$ ,  $Dywwv$ ,  $Dytwp$ , and  $A_I$ , are site-specific.
- (2) The equation assumes a default  $S_T$  value for background plus local sources, rather than an  $S_T$  value for urban sources. If a specific site is located in an urban area, the use of the latter  $S_T$  value may be more appropriate. Specifically, the  $S_T$  value for urban sources is about one order of magnitude greater than that for background plus local sources and would result in a lower calculated  $F_v$  value; however, the  $F_v$  value is likely to be only a few percent lower.

**Equation**

$$L_{RI} = Q \cdot [F_v \cdot Dywwv + (1 - F_v) \cdot Dytwp] \cdot A_I$$

**For mercury modeling:**

$$L_{RI_{Mercury}} = 0.48Q_{TotalMercury} \cdot [F_{v_{Hg^{2+}}} \cdot Dywwv + (1.0 - F_{v_{Hg^{2+}}}) \cdot Dytwp] \cdot A_I$$

In calculating  $L_{RI}$  for mercury compounds,  $L_{RI}(Mercury)$  is calculated as shown above using the total mercury emission rate ( $Q$ ) measured at the stack and  $F_v$  for mercuric chloride ( $F_v = 0.85$ ). As presented below, the calculated  $L_{RI}(Mercury)$  value is apportioned into the divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) forms based on a 85%  $Hg^{2+}$  and 15% MHg speciation split in the water body (see Chapter 2).

$$\begin{aligned} L_{RI}(Hg^{2+}) &= 0.85 L_{RI} Mercury \\ L_{RI}(MHg) &= 0.15 L_{RI} Mercury \end{aligned}$$

After calculating species specific  $L_{RI}$  values, divalent and methyl mercury should continue to be modeled throughout Appendix B equations as individual COPCs.

## TABLE B-2-4

### IMPERVIOUS RUNOFF LOAD TO WATER BODY (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 3 of 3)

#### REFERENCES AND DISCUSSION

Bidleman, T.F. 1988. "Atmospheric Processes." *Environmental Science and Technology*. Volume 22. Number 4. Pages 361-367.

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is a reference source for the equation in Table B-2-4. This document also recommends using the equations in Bidleman (1988) to calculate  $F_v$  values for all organics other than dioxins (PCDD/PCDFs). However, the document does not present a recommendation for dioxins. Finally, this document states that metals are generally entirely in the particulate phase ( $F_v = 0$ ) except for mercury, which is assumed to be entirely in the vapor phase. The document does not state whether  $F_v$  for mercury should be calculated by using the equations in Bidleman (1988).

U.S. EPA. 1994. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document is a reference source for the equation in Table B-2-4.

TABLE B-2-5

**PERVIOUS RUNOFF LOAD TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 5)

**Description**

This equation calculates the average runoff load to the water body from pervious soil surfaces in the watershed.

Uncertainties associated with this equation include the following:

- (1) To the extent that site-specific or local average annual surface runoff information is not available, default or estimated values may not accurately represent site-specific or local conditions. As a result,  $L_R$  may be under- or overestimated to an unknown degree.
- (2) The recommended range of soil bulk density values may not accurately represent site-specific soil conditions; specifically, this range may under- or overestimate site-specific soil conditions to an unknown degree.
- (3) The default  $\theta_{sw}$  values may not accurately reflect site-specific or local conditions; therefore,  $L_R$  may be under- or overestimated to a small extent, based on the limited range of values.
- (4) Various uncertainties are associated with  $C_s$ ; see the equation in Table B-1-1.

**Equation**

$$L_R = RO \cdot (A_L - A_I) \cdot \frac{C_s \cdot BD}{\theta_{sw} + Kd_s \cdot BD} \cdot 0.01$$

**For mercury modeling:**

For mercury modeling,  $L_{R(Initial)}$  values are calculated for divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) using their respective  $C_s$  and  $Kd_s$  values; then as indicated below, these values are apportioned based on a 85%  $Hg^{2+}$  and 15% MHg speciation split in the water body (see Chapter 2).

$$L_{R_{Hg^{2+}}} = L_{R_{Hg^{2+}}(Initial)} \cdot 0.85$$

$$L_{R_{MHg}} = L_{R_{MHg}(Initial)} + (L_{R_{Hg^{2+}}(Initial)} \cdot 0.15)$$

After calculating species specific  $L_R$  values, divalent and methyl mercury should continue to be modeled throughout Appendix B equations as individual COPCs.

| $RO$     | Average annual surface runoff                       | cm/yr          | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific. According to U.S. EPA (1993), U.S. EPA (1994), and NC DEHNR (1997), average annual surface runoff can be estimated by using the <i>Water Atlas of the United States</i> (Geraghty, Miller, Van der Leeden, and Troise 1973). According to NC DEHNR, (1997), more detailed, site-specific procedures for estimating the amount of surface runoff, such as those based on the U.S. Soil Conservation Service CNE may also be used. U.S. EPA (1985) is cited as an example of such a procedure.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) To the extent that site-specific or local average annual surface runoff information is not available, default or estimated values may not accurately represent site-specific or local conditions. As a result, <math>K_R</math> may be under- or overestimated to an unknown degree.</p> |
| $A_L$    | Total watershed area receiving COPC deposition      | m <sup>2</sup> | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific (see Chapter 4). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

TABLE B-2-5

**PERVIOUS RUNOFF LOAD TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 3 of 5)

| Variable      | Description                      | Units                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|----------------------------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $BD$          | Soil bulk density                | $\text{g/cm}^3$                | <p align="center"><b>1.5</b></p> <p>This variable is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil (Hillel 1980), as summarized in U.S. EPA (1990). A range of 0.83 to 1.84 was originally cited in Hoffman and Baes (1979). U.S. EPA (1994) recommended a default soil bulk density value of <math>1.5 \text{ g/cm}^3</math>, based on a mean value for loam soil from Carsel, Parrish, Jones, Hansen, and Lamb (1988). The value of <math>1.5 \text{ g/cm}^3</math> also represents the midpoint of the "relatively narrow range" for <math>BD</math> of 1.2 to <math>1.7 \text{ g/cm}^3</math>.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended range of soil dry bulk density values may not accurately represent site-specific soil conditions.</p>                            |
| $\theta_{sw}$ | Soil volumetric water content    | $\text{mL/cm}^3$               | <p align="center"><b>0.2</b></p> <p>This variable depends on the available water and on soil structure. <math>\theta_{sw}</math> can be estimated as the midpoint between a soil's field capacity and wilting point, if a representative watershed soil can be identified. However, U.S. EPA OSW recommends the use of <math>0.2 \text{ mL/cm}^3</math> as a default value. This value is the midpoint of the range 0.1 (very sandy soils) to 0.3 (heavy loam/clay soils) recommended by U.S. EPA (1993) (no source or reference is provided for this range) and is consistent with U.S. EPA (1994).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default <math>\theta_{sw}</math> values may not accurately reflect site-specific or local conditions; therefore, <math>L_R</math> may be under- or overestimated to a small extent, based on the limited range of values.</p> |
| $Kd_s$        | Soil-water partition coefficient | $\text{cm}^3/\text{g}$         | <p align="center"><b>Varies (see Appendix A-2)</b></p> <p>This variable is COPC-specific and should be determined from the COPC tables in Appendix A-2.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Uncertainties associated with this parameter will be limited if <math>Kd_s</math> values are calculated as described in Appendix A-2.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| $0.01$        | Units conversion factor          | $\text{kg-cm}^2/\text{mg-m}^2$ |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## TABLE B-2-5

### PERVIOUS RUNOFF LOAD TO WATER BODY (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 4 of 5)

#### REFERENCES AND DISCUSSION

Carsel, R.F., R.S. Parrish, R.L. Jones, J.L. Hansen, and R.L. Lamb. 1988. "Characterizing the Uncertainty of Pesticide Leaching in Agricultural Soils." *Journal of Contaminant Hydrology*. Volume 2: pages 11-24.

Geraghty, J.J., D.W. Miller, F. Van der Leeden, and F.L. Troise. 1973. *Water Atlas of the United States*. Water Information Center. Port Washington, New York.

This document is cited by U.S. EPA (1993), U.S. EPA (1994), and NC DEHNR (1997) as a reference for calculating average annual runoff,  $RO$ . Specifically, this reference provides maps with isolines of annual average surface water runoff, which is defined as all flow contributions to surface water bodies, including direct runoff, shallow interflow, and ground water recharge. Because these volumes are total contributions and not only surface runoff, U.S. EPA (1994) notes that they need to be reduced to estimate surface runoff. U.S. EPA (1994) recommends a reduction of 50 percent.

Hillel, D. 1980. *Fundamentals of Soil Physics*. Academic Press, Inc. New York.

This document is cited by U.S. EPA (1990) for the statement that dry soil bulk density,  $BD$ , is affected by soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil.

Hoffman, F.O., and C.F. Baes. 1979. *A Statistical Analysis of Selected Parameters for Predicting Food Chain Transport and Internal Dose of Radionuclides*. ORNL/NUREG/TM-882.

This document presents a soil bulk density,  $BD$ , range of 0.83 to 1.84 g/cm<sup>3</sup>.

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Assessments for Hazardous Waste Combustion Units*. January.

This document is one of the source documented that cites the use of the equation in Table B-2-5. However, the document is not the original source of this equation. This document also recommends the following:

- Estimation of average annual runoff,  $RO$  (cm/yr), by using the *Water Atlas of the United States* (Geraghty, Miller, Van der Leeden, and Troise 1973) or site-specific procedures, such as the U.S. Soil Conservation Service CNE; U.S. EPA (1985) is cited as an example of the use of the CNE
- A default value of 0.2 cm<sup>3</sup>/cm<sup>3</sup> for soil volumetric content ( $\theta_{sw}$ )

U.S. EPA. 1985. *Water Quality Assessment: A Screening Procedures for Toxic and Conventional Pollutants in Surface and Ground Water - Part I (Revised - 1985)*. Environmental Research Laboratory. Athens, Georgia. EPA/600/6-85/002a. September.

## TABLE B-2-5

### PERVIOUS RUNOFF LOAD TO WATER BODY (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 5 of 5)

U.S. EPA. 1990. *Interim Final Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Environmental Criteria and Assessment Office. Office of Research and Development. EPA 600-90-003. January.

This document cites Hillel (1980) for the statement that only soil bulk density,  $BD$ , is affected by the soil structure, such as loosened or compaction of the soil, depending on the water and clay content of the soil.

U.S. EPA. 1993. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document is a source of COPC-specific (inorganics only)  $Kd_s$  values used to develop a range (2 to 280,000 mL/g) of  $Kd_s$  values. This document also recommends a range of soil volumetric water content ( $\theta_{sw}$ ) of 0.1 cm<sup>3</sup>/cm<sup>3</sup> (very sandy soils) to 0.3 cm<sup>3</sup>/cm<sup>3</sup> (heavy loam/clay soils); however, no source or reference is provided for this range.

U.S. EPA. 1994. *Revised Draft Guidance of Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes*. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document recommends (1) a default soil bulk density value of 1.5 g/cm<sup>3</sup>, based on a mean value for loam soil from Carsel, Parrish, Jones, Hansen, and Lamb (1988), and (2) a default soil volumetric water content,  $\theta_{sw}$ , value of 0.2 cm<sup>3</sup>/cm<sup>3</sup>, based on U.S. EPA (1993).

TABLE B-2-6

**EROSION LOAD TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 6)

**Description**

This equation calculates the load to the water body from soil erosion.

Uncertainties associated with this equation include the following:

- (1) Most of the uncertainties associated with the variables, specifically those for  $X_e$ ,  $A_L$ ,  $A_I$ , and  $C_s$ , are site-specific.
- (2) Uncertainties associated with the remaining variables are not expected to be significant, primarily because of the narrow ranges of probable values for these variables or the use of well-established estimation procedures ( $Kd_s$ ).

**Equation**

$$L_E = X_e \cdot (A_L - A_I) \cdot SD \cdot ER \cdot \frac{C_s \cdot Kd_s \cdot BD}{\theta_{sw} + Kd_s \cdot BD} \cdot 0.001$$

**For mercury modeling:**

For mercury modeling,  $L_{E(Initial)}$  values are calculated for divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) using their respective  $C_s$  and  $Kd_s$  values; then as indicated below, these values are apportioned based on a 85%  $Hg^{2+}$  and 15% MHg speciation split in the water body (see Chapter 2).

$$L_{E_{Hg^{2+}}} = L_{E_{Hg^{2+}}(Initial)} \cdot 0.85$$

$$L_{E_{MHg}} = L_{E_{MHg}(Initial)} + (L_{E_{Hg^{2+}}(Initial)} \cdot 0.15)$$

After calculating species specific  $L_E$  values, divalent and methyl mercury should continue to be modeled throughout Appendix B equations as individual COPCs.

| Variable | Description                                         | Units                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|-----------------------------------------------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $L_E$    | Soil erosion load                                   | g/yr                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| $X_e$    | Unit soil loss                                      | kg/m <sup>2</sup> -yr | <p style="text-align: center;"><b>Varies (calculated - Table B-2-7)</b></p> <p>This variable is site-specific, and is calculated by using the equation in Table B-2-7.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) All of the equation variables (see Table B-2-7) are site-specific. Use of default values rather than site-specific values, for any or all of these variables, will result in estimates of unit soil loss, <math>X_e</math>, that are under- or overestimated to some degree. The range of <math>X_e</math> calculated on the basis of default values spans slightly more than one order of magnitude (0.6 to 36.3 kg/m<sup>2</sup>-yr).</p> |
| $A_L$    | Total watershed area receiving COPC deposition      | m <sup>2</sup>        | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific (see Chapter 4). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| $A_I$    | Impervious watershed area receiving COPC deposition | m <sup>2</sup>        | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific (see Chapter 4). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| $SD$     | Sediment delivery ratio                             | unitless              | <p style="text-align: center;"><b>Varies (calculated - Table B-2-8)</b></p> <p>This value is site-specific and is calculated by using the equation in Table B-2-8.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended default values for the variables <math>a</math> and <math>b</math> (empirical intercept coefficient and empirical slope coefficient, respectively) are average values, based on a review of sediment yields from various watersheds. These default values may not accurately represent site-specific watershed conditions and, therefore, may contribute to the under- or over estimation of <math>L_E</math>.</p>              |

TABLE B-2-6

**EROSION LOAD TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 3 of 6)

| Variable                         | Description                      | Units              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------|----------------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ER</i>                        | Soil enrichment ratio            | unitless           | <p style="text-align: center;"><b>1 to 3</b><br/> <b>Inorganic COPCs: 1</b><br/> <b>Organic COPCs: 3</b></p> <p>COPC enrichment occurs because lighter soil particles erode more than heavier soil particles and concentrations of organic COPCs which is a function of organic carbon content of sorbing media, are expected to be higher in eroded material than in-situ soil (U.S. EPA 1993). In the absence of site-specific data, U.S. EPA OSW recommends a default value of 3 for organic COPCs and 1 for inorganic COPCs. This is consistent with other U.S. EPA guidance (1993), which recommends a range of 1 to 5 and a value of 3 as a "reasonable first estimate". This range has been used for organic matter, phosphorus, and other soil-bound COPCs (U.S. EPA 1993); however, no sources or references were provided for this range. <i>ER</i> is generally higher in sandy soils than in silty or loamy soils (U.S. EPA 1993).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default <i>ER</i> value may not accurately reflect site-specific conditions; therefore, <math>L_E</math> may be over- or underestimated to an unknown, but relatively small, extent.</p> |
| <i>C<sub>s</sub></i>             | COPC concentration in soil       | mg/kg              | <p style="text-align: center;"><b>Varies (calculated - Table B-1-1)</b></p> <p>This value is COPC-and site-specific and should be calculated using the equation in Table B-1-1. For calculation of <i>C<sub>s</sub></i> in watersheds, the maximum or average of air parameter values at receptor grid nodes located within the watershed may be used (see Chapter 4). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>K<sub>d<sub>s</sub></sub></i> | Soil-water partition coefficient | cm <sup>3</sup> /g | <p style="text-align: center;"><b>Varies (see Appendix A-2)</b></p> <p>This variable is COPC-specific and should be determined from the COPC tables in Appendix A-2.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Uncertainties associated with this parameter will be limited if <i>K<sub>d<sub>s</sub></sub></i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

TABLE B-2-6

**EROSION LOAD TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

| Variable      | Description                   | Units            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|-------------------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>BD</i>     | Soil bulk density             | $\text{g/cm}^3$  | <p style="text-align: center;"><b>1.5</b></p> <p>This variable is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil (Hillel 1980), as summarized in U.S. EPA (1990). A range of 0.83 to 1.84 was originally cited in Hoffman and Baes (1979). U.S. EPA (1994a) recommended a default soil bulk density value of 1.5 <math>\text{g/cm}^3</math>, based on a mean value for loam soil from Carsel, Parrish, Jones, Hansen, and Lamb (1988). The value of 1.5 <math>\text{g/cm}^3</math> also represents the midpoint of the "relatively narrow range" for <i>BD</i> of 1.2 to 1.7 <math>\text{g/cm}^3</math>.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended range of soil dry bulk density values may not accurately represent site-specific soil conditions.</p>                                     |
| $\theta_{sw}$ | Soil volumetric water content | $\text{mL/cm}^3$ | <p style="text-align: center;"><b>0.2</b></p> <p>This variable depends on the available water and on soil structure. <math>\theta_{sw}</math> can be estimated as the midpoint between a soil's field capacity and wilting point, if a representative watershed soil can be identified. However, U.S. EPA OSW recommends the use of 0.2 <math>\text{cm}^3</math> as a default value. This value is the midpoint of the range of 0.1 (very sandy soils), to 0.3 (heavy loam/clay soils), recommended by U.S. EPA (1993) (no source or reference is provided for this range) and is consistent with U.S. EPA (1994).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default <math>\theta_{sw}</math> values may not accurately reflect site-specific or local conditions; therefore, <math>L_E</math> may be under- or overestimated to a small extent, based on the limited range of values.</p> |
| 0.001         | Units conversion factor       | $\text{g/mg}$    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## TABLE B-2-6

### EROSION LOAD TO WATER BODY (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 5 of 6)

#### REFERENCES AND DISCUSSION

This document cites Hillel (1980) for the statement that dry soil bulk density,  $BD$ , is affected by the soil structure, such as looseness or compaction of the soil, depending on the water and clay content of the soil.

U.S. EPA. 1993. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November 1993.

This document is the source of the recommended range of COPC enrichment ratio,  $ER$ , values. This range, 1 to 5, has been used for organic matter, phosphorous, and other soil-based COPCs. This document recommends a value of 3 as a "reasonable first estimate," and states that COPC enrichment occurs because lighter soil particles erode more than heavier soil particles. Lighter soil particles have higher surface-area-to-volume ratios and are higher in organic matter content. Therefore, concentrations of organic COPCs, which are a function of the organic carbon content of sorbing media, are expected to be higher in eroded material than in in-situ soil.

This document is also the source of the following:

- COPC-specific (inorganics only)  $K_d$  values used to develop a proposed range (0 to 280,000 mL/g) of  $K_d$  values

**TABLE B-2-6**

**EROSION LOAD TO WATER BODY  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

**(Page 6 of 6)**

- A range of soil volumetric water content ( $\theta_{sw}$ ) values of 0.1 mL/cm<sup>3</sup> (very gravelly soils) to 0.3 mL/cm<sup>3</sup> (heavy loam/clay soils); however, no source or reference is provided for this range.

U.S. EPA. 1994. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes*. Attachment C, *Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document recommends (1) a default soil bulk density value of 1.5 g/cm<sup>3</sup>, based on a mean value for loam soil from Carsel, Parrish, Jones, Hansen, and Lamb (1988), and (2) a default soil volumetric water content,  $\theta_{sw}$ , value of 0.2 cm<sup>3</sup>, based on U.S. EPA (1993).

TABLE B-2-7

**UNIVERSAL SOIL LOSS EQUATION (USLE)  
(SOIL EQUATIONS)**

**(Page 1 of 5)**

**Description**

This equation calculates the soil loss rate from the watershed by using the Universal Soil Loss Equation (USLE); the result is used in the soil erosion load equation in Table B-2-6. Estimates of unit soil loss,  $X_e$ , should be determined specific to each watershed evaluated. Information on determining site- and watershed-specific values for variables used in calculating  $X_e$  is provided in U.S. Department of Agriculture (U.S. Department of Agriculture 1997) and U.S. EPA guidance (U.S. EPA 1985). Uncertainties associated with this equation include the following:

- (1) All of the equation variables are site-specific. Use of site-specific values will result in estimates of unit soil loss,  $X_e$ , that are under- or overestimated to some unknown degree.

**Equation**

$$X_e = RF \cdot K \cdot LS \cdot C \cdot PF \cdot \frac{907.18}{4047}$$

| Variable | Description                         | Units                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------|-------------------------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $X_e$    | Unit soil loss                      | kg/m <sup>2</sup> -yr |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| $RF$     | USLE rainfall (or erosivity) factor | yr <sup>-1</sup>      | <p style="text-align: center;"><b>50 to 300 (site-specific)</b></p> <p>This value is site-specific and is derived on a storm-by-storm basis. As cited in U.S. EPA (1993b), average annual values have been compiled regionally by Wischmeier and Smith (1978). The recommended range reflects these compiled values.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The range of average annual rainfall factors (50 to 300) from Wischmeier and Smith (1978) may not accurately reflect site-specific conditions. Therefore, unit soil loss, <math>X_e</math>, may be under- or overestimated.</p> |

TABLE B-2-7

(SOIL EQUATIONS)**

(Page 2 of 5)

| Variable  | Description              | Units    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|--------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>K</i>  | USLE erodibility factor  | ton/acre | <p style="text-align: center;"><b>Varies</b></p> <p>This value is site-specific. U.S. EPA OSW recommends the use of current guidance (U.S. Department of Agriculture 1997; U.S. EPA 1985) in determining watershed-specific values for this variable based on site-specific information. A default value of 0.36, as cited in U.S. EPA (1994), was based on a soil organic matter content of 1 percent (Droppo, Streng, Buck, Hoopes, Brockhaus, Walter, and Whelan 1989), and chosen to be representative of a whole watershed.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The determination and use of site-specific values for the USLE soil erodibility factor, <i>K</i>, may not accurately represent site-specific conditions. Therefore, use of this value may cause unit soil loss, <math>X_e</math>, to be under- or overestimated.</p> |
| <i>LS</i> | USLE length-slope factor | unitless | <p style="text-align: center;"><b>Varies</b></p> <p>This value is site-specific. U.S. EPA OSW recommends the use of current guidance (U.S. Department of Agriculture 1997; U.S. EPA 1985) in determining watershed-specific values for this variable based on site-specific information. A value of 1.5, as cited in U.S. EPA (1994), reflects a variety of possible distance and slope conditions (U.S. EPA 1988), and was chosen to be representative of a whole watershed.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The determination and use of site-specific values for the USLE length-slope factor, <i>LS</i>, may not accurately represent site-specific conditions. Therefore, use of this value may cause unit soil loss, <math>X_e</math>, to be under- or overestimated.</p>                                                       |

TABLE B-2-7

**UNIVERSAL SOIL LOSS EQUATION (USLE)  
(SOIL EQUATIONS)**

(Page 3 of 5)

| Variable  | Description                     | Units                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|---------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>C</i>  | USLE cover management factor    | unitless             | <p style="text-align: center;"><b>Varies</b></p> <p>This value is site-specific. U.S. EPA OSW recommends the use of current guidance (U.S. Department of Agriculture 1997; U.S. EPA 1985) in determining watershed-specific values for this variable based on site-specific information. The range of values up to 0.1 reflect dense vegetative cover, such as pasture grass; values from 0.1 to 0.7 reflect agricultural row crops; and a value of 1.0 reflects bare soil (U.S. EPA 1993b). U.S. EPA (1993a) recommended a value of 0.1 for both grass and agricultural crops. This range of values was also cited in NC DEHNR (1997). However, U.S. EPA (1994) and NC DEHNR (1997) both recommend a default value of 0.1 to be representative of a whole watershed.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The determination and use of site-specific values for USLE cover management factor, <i>C</i>, may not accurately represent site-specific conditions. Therefore, use of default value for <i>C</i> may result in the under- or overestimation of unit soil loss, <math>X_e</math>.</p> |
| <i>PF</i> | USLE supporting practice factor | unitless             | <p style="text-align: center;"><b>Varies</b></p> <p>This value is site-specific. U.S. EPA OSW recommends the use of current guidance (U.S. Department of Agriculture 1997; U.S. EPA 1985) in determining watershed-specific values for this variable based on site-specific information. A default value of 1.0, which conservatively represents the absence of any erosion or runoff control measures, was cited in U.S. EPA (1993a; 1994) and NC DEHNR (1997).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The determination and use of site-specific values for the USLE supporting practice factor, <i>PF</i>, may not accurately represent site-specific conditions. Therefore, resulting in the under- or overestimation of unit soil loss, <math>X_e</math>.</p>                                                                                                                                                                                                                                                                                                                                 |
| 907.18    | Conversion factor               | kg/ton               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### UNIVERSAL SOIL LOSS EQUATION (USLE) (SOIL EQUATIONS)

(Page 4 of 5)

#### REFERENCES AND DISCUSSION

Droppo, J.G. Jr., D.L. Streng, J.W. Buck, B.L. Hoopes, R.D. Brockhaus, M.B. Walter, and G. Whelan. 1989. *Multimedia Environmental Pollutant Assessment System (MEPAS) Application Guidance: Volume 2-Guidelines for Evaluating MEPAS Input Parameters*. Pacific Northwest Laboratory. Richland, Washington. December.

This document is cited by U.S. EPA 1994 and NC DEHNR 1997 as the reference source for the default USLE erodibility factor value of 0.36, based on a soil organic matter content of 1 percent.

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document recommends the following:

- A USLE erodibility factor, *K*, value of 0.36 ton/acre
- A USLE length-slope factor, *LS*, value of 1.5 (unitless)
- A range of USLE cover management factor, *C*, values of 0.1 to 1; it also recommends a default value of 0.1 to be representative of a whole watershed, not just an agricultural field.
- A USLE supporting practice factor, *P*, value of 1

U.S. Department of Agriculture. 1997. *Predicting Soil Erosion by Water: A Guide to Conservation Planning With the Revised Universal Soil Loss Equation (RUSLE)*. Agricultural Research Service, Agriculture Handbook Number 703. January.

U.S. EPA. 1985. *Water Quality Assessment: A Screening Procedure for Toxic and Conventional Pollutants in Surface and Ground Water—Part I (Revised)*. ORD. Athens, Georgia. EPA/600/6-85/002a.

U.S. EPA. 1988. *Superfund Exposure Assessment Manual*. Office of Solid Waste. Washington, D.C. April.

This document is cited by U.S. EPA 1994 and NC DEHNR 1997 as the reference source for the USLE length-slope factor value of 1.5. This value reflects a variety of possible distance and slope conditions and was chosen to be representative of a whole watershed, not just an agricultural field.

U.S. EPA. 1993a. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions. Working Group Recommendations*. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document cites Wischmeier and Smith (1978) as the source of average annual USLE rainfall factors, *RF*, and states that annual values range from less than 50 for the arid western United States to greater than 300 for the southeast.

This document also recommends the following:

- A USLE cover management factor, *C*, of 0.1 for both grass and agricultural crops
- A USLE supporting practice factor, *P*, of 1, based on the assumed absence of any erosion or runoff control measures

## TABLE B-2-7

### UNIVERSAL SOIL LOSS EQUATION (USLE) (SOIL EQUATIONS)

(Page 5 of 5)

U.S. EPA. 1993b. *Review Draft Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustion Emissions*. Office of Health and Environmental Assessment. Office of Research and Development. EPA-600-AP-93-003. November 10.

This document discusses the USLE cover management factor. This factor, *C*, primarily reflects how erosion is influenced by vegetative cover and cropping practices, such as planting across slope rather than up and down slope. This document discusses a range of *C* values for 0.1 to 1; values greater than 0.1 but less than 0.2 are appropriate for agricultural row crops, and a value of 1 is appropriate for sites mostly devoid of vegetation.

U.S. EPA. 1994. *Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document recommends the following:

- A USLE erodibility factor, *K*, value of 0.36 ton/acre
- A USLE length-slope factor, *LS*, value of 1.5 (unitless)
- A range of USLE cover management factor, *C*, values of 0.1 to 1; it recommends a default value of 0.1 to be representative of a whole watershed, not just an agricultural field.
- A USLE supporting practice factor, *P*, value of 1

Wischmeire, W.H., and D.D. Smith. 1978. *Predicting Rainfall Erosion Losses—A Guide to Conservation Planning*. Agricultural Handbook No. 537. U.S. Department of Agriculture Washington, D.C.

This document is cited by U.S. EPA (1993) as the source of average annual USLE rainfall factors, *RF*, compiled regionally. According to U.S. EPA (1993), annual values range from less than 50 for the arid western United States to greater than 300 for the southeast.

| <i>b</i> | Empirical slope coefficient | unitless | <p><b>0.125</b></p> <p>As cited in U.S. EPA (1993), this variable is an empirical constant based on the research of Vanoni (1975), which concludes that sediment delivery ratios vary approximately with the <math>-(1/8)</math> power of the drainage area. The use of this value is consistent with U.S. EPA (1994a and 1994b) and NC DEHNR (1997). U.S. EPA has not completed its review of Vanoni (1975).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended default empirical slope coefficient, <i>b</i>, value is based on a review of sediment yields from various watersheds. This single default value may not accurately represent site-specific watershed conditions. As a result, use of this default value may under- or overestimate the watershed sediment delivery ratio, <i>SD</i>.</p> |

### SEDIMENT DELIVERY RATIO (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 4 of 4)

#### REFERENCES AND DISCUSSION

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is cited as one of the reference source documents for the empirical intercept coefficient,  $a$ , and empirical slope coefficient,  $b$ , values. This document cites U.S. EPA (1993) as the source of its information.

U.S. EPA. 1993. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November.

This document is cited as one of the reference source documents for the empirical intercept coefficient,  $a$ , and empirical slope coefficient,  $b$ , values. This document cites Vanoni (1975) as its source of information.

U.S. EPA. 1994a. *Draft Guidance for Performing Screening Level Risk Analyses at Combustor Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. April 15.

This document is cited as one of the reference source documents for the empirical intercept coefficient,  $a$ , and empirical slope coefficient,  $b$ , values. This document does not identify Vanoni (1975) as the source of its information.

U.S. EPA. 1994b. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document is cited as one of the reference source documents for the empirical intercept coefficient,  $a$ , and the empirical slope coefficient,  $b$ , values. This document cites U.S. EPA (1993) as the source of its information.

Vanoni, V.A. 1975. *Sedimentation Engineering*. American Society of Civil Engineers. New York, New York. Pages 460-463.

This document is cited by U.S. EPA (1993) as the source of the equation in Table B-2-8 and the empirical intercept coefficient,  $a$ , and empirical slope coefficient,  $b$ , values. Based on various studies of sediment yields from watersheds, this document concludes that the sediment delivery ratios vary approximately with the  $-(1/8)$  power of the drainage ratio.

| <p>This equation calculates the total water body concentration; including the water column and the bed sediment.</p> <p>Uncertainties associated with this equation include the following:</p> <ol style="list-style-type: none"> <li>(1) The default variable values recommended for use in the equation in Table B-2-9 may not accurately represent site-specific water body conditions. The degree of uncertainty associated with the variables <math>Vf_x</math>, <math>A_w</math>, <math>d_{wc}</math>, and <math>d_{bs}</math> is expected to be limited either because the probable ranges for these variables are narrow or information allowing accurate estimates is generally available.</li> <li>(2) Uncertainty associated with <math>f_{wc}</math> is largely the result of uncertainty associated with default organic carbon (OC) content values and may be significant in specific instances. Uncertainties associated with the total core load into water body (<math>L_T</math>) and overall total water body core dissipation rate constant (<math>k_{wt}</math>) may also be significant in some instances because of the summation of many variable-specific uncertainties.</li> </ol> |                                                                               |                                          |                                                                                                                                                                                                                                                                                                                                                                                |
| Equation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                               |                                          |                                                                                                                                                                                                                                                                                                                                                                                |

| Variable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Description                                                                   | Units                                    | Value                                                                                                                                                                                                                                                                                                                                                                          |
| $C_{wtot}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Total water body COPC concentration (including water column and bed sediment) | g/m <sup>3</sup><br>(equivalent to mg/L) |                                                                                                                                                                                                                                                                                                                                                                                |
| $L_T$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Total COPC load to the water body (including deposition, runoff, and erosion) | g/yr                                     | <p><b>Varies (calculated - Table B-2-1)</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-1.</p> <p>Uncertainties associated with <math>L_{DEP}</math>, <math>L_{DIP}</math>, <math>L_{RI}</math>, <math>L_R</math>, and <math>L_E</math>, as presented in Table B-2-1, are also associated with <math>L_T</math>.</p> |

TABLE B-2-9

**TOTAL WATER BODY CONCENTRATION  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 2 of 4)

| Variable | Description                                                                     | Units              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------|---------------------------------------------------------------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $V_{fx}$ | Average volumetric flow rate through water body                                 | m <sup>3</sup> /yr | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific and should be an annual average.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Use of default average volumetric flow rate (<math>V_{fx}</math>) information may not accurately represent site-specific conditions, especially for those water bodies for which flow rate information is not readily available. Therefore, use of default <math>V_{fx}</math> values may contribute to the under- or overestimation of total water body COPC concentration, <math>C_{wtot}</math>.</p>                                                                                                                                                                                                                                                                                                                                                                                                      |
| $f_{wc}$ | Fraction of total water body COPC concentration that occurs in the water column | unitless           | <p style="text-align: center;"><b>0 to 1 (calculated - Table B-2-10)</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-10.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default values for the variables in the equation in Table B-2-10 may not accurately represent site- and water body - specific conditions. However, the range of several variables—including <math>d_{bs}</math>, <math>C_{BS}</math>, and <math>\theta_{bs}</math>—is relatively narrow. Other variables, such as <math>d_{wc}</math> and <math>d_z</math>, can be reasonably estimated on the basis of generally available information. The largest degree of uncertainty may be introduced by the default medium-specific organic carbon (OC) content values. Because OC content values may vary widely in different locations in the same medium, by using default values may result in insignificant uncertainty in specific cases.</p>               |
| $k_{wt}$ | Overall total water body COPC dissipation rate constant                         | yr <sup>-1</sup>   | <p style="text-align: center;"><b>Varies (calculated - Table B-2-11)</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-11.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) All of the variables in the equation in Table B-2-11 are site-specific; therefore, the use of default values for any or all of these variables will contribute to the under- or overestimation of <math>C_{wtot}</math>. The degree of uncertainty associated with the variable <math>k_b</math> is expected to be under one order of magnitude and is associated largely with the estimation of the unit soil loss, <math>X_e</math>, values for the variables <math>f_{wc}</math>, <math>k_v</math>, and <math>f_{bs}</math> are dependent on medium-specific estimates of OC content. Because OC content can vary widely for different locations in the same medium, uncertainty associated with these three may be significant in specific instances.</p> |

TABLE B-2-9

**TOTAL WATER BODY CONCENTRATION  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 3 of 4)

| Variable | Description                           | Units                                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| $A_w$    | Water body surface area               | m <sup>2</sup><br>(average value for the entire year) | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific (see Chapter 4). The value selected is assumed to represent an average value for the entire year.</p> <p>Uncertainties associated with this variable are site-specific and expected to be limited, because maps, aerial photographs, and other resources from which water body surface areas can be measured, are readily available.</p>                                                                                                                                                                                                                                                                                                         |
| $d_{wc}$ | Depth of water column                 | m<br>(average value for the entire year)              | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific and should be an average annual value.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Use of default depth of water column, <math>d_{wc}</math>, values may not accurately reflect site-specific conditions, especially for those water bodies for which depth of water column information is unavailable or outdated. Therefore, use of default <math>d_{wc}</math> values may contribute to the under-or overestimation of total water body COPC concentration, <math>C_{wtot}</math>.</p>                                                                                                                      |
| $d_{bs}$ | Depth of upper benthic sediment layer | m                                                     | <p style="text-align: center;"><b>0.03</b></p> <p>This variable is site-specific. The value selected is assumed to represent an average value for the entire year. U.S. EPA OSW recommends a default upper benthic sediment depth of 0.03 meter, which is consistent with U.S. EPA (1994) and NC DEHNR (1997) guidance. This range was cited by U.S. EPA (1993); however, no reference was cited for this range.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Use of default depth of upper benthic layer, <math>d_{bs}</math>, values may not accurately represent site-specific water body conditions. However, based on the narrow recommended range, any uncertainty introduced is expected to be limited.</p> |

## TABLE B-2-9

### TOTAL WATER BODY CONCENTRATION (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 4 of 4)

#### REFERENCES AND DISCUSSION

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is also cited as one of the reference source documents for the default depth of upper benthic layer value. The default value is the midpoint of an acceptable range. This document cites U.S. EPA (1993) as its source of information for the range of values for the depth of the upper benthic layer.

U.S. EPA. 1993. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document is cited by NC DEHNR (1997) and U.S. EPA (1994) as the source of the range and default value for the depth of the upper benthic layer ( $d_{bs}$ ).

U.S. EPA. 1994. *Draft Guidance for Performing Screening Level Risk Analyses at Combustor Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. April 15.

This document is cited as one of the reference source documents for the default depth of the upper benthic layer value. The default value is the midpoint of an acceptable range. This document cites U.S. EPA (1993) as its source of information for the range of values for the depth of the upper benthic layer.

TABLE B-2-10

**FRACTION IN WATER COLUMN AND BENTHIC SEDIMENT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 5)

**Description**

This equation calculates the fraction of total water body concentration occurring in the water column and the bed sediments.

Uncertainties associated with this equation include the following:

- (1) The default variable values may not accurately represent site-specific water body conditions. However, the range of several variables—including  $d_{bs}$ ,  $BS$ , and  $\theta_{bs}$ —is relatively narrow. Other variables, such as  $d_{wc}$  and  $d_z$ , can be reasonably estimated on the basis of generally available information. The largest degree of uncertainty may be introduced by the default medium-specific  $OC$  content values.  $OC$  content values can vary widely for different locations in the same medium. Therefore, the use of default values may introduce significant uncertainty in some cases.

**Equations**

$$f_{wc} = \frac{(1 + Kd_{sw} \cdot TSS \cdot 10^{-6}) \cdot d_{wc} / d_z}{(1 + Kd_{sw} \cdot TSS \cdot 1 \times 10^{-6}) \cdot d_{wc} / d_z + (\theta_{bs} + Kd_{bs} \cdot BS) \cdot d_{bs} / d_z}$$

$$f_{bs} = 1 - f_{wc}$$

**For mercury modeling:**

The fraction in water column ( $f_{wc}$ ) is calculated for divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) using their respective  $Kd_{sw}$  values and  $Kd_{bs}$  values. The fraction in benthic sediment ( $f_{bs}$ ) is calculated for divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) using their respective  $f_{wc}$  values.

| Variable | Description                                                             | Units    | Value |
|----------|-------------------------------------------------------------------------|----------|-------|
| $f_{wc}$ | Fraction of total water body COPC concentration in the water column     | unitless |       |
| $f_{bs}$ | Fraction of total water body COPC concentration in the benthic sediment | unitless |       |

| Variable | Description                           | Units                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------|---------------------------------------|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $d_{bs}$ | Depth of upper benthic sediment layer | m                                         | <p style="text-align: center;"><b>0.03</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends a default upper benthic sediment depth of 0.03 meter, which is consistent with U.S. EPA (1994) and NC DEHNR (1997) guidance. This range was cited by U.S. EPA (1993b); however, no reference was cited for this range.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Use of default depth of upper benthic layer, <math>d_{bs}</math>, values may not accurately represent site-specific water body conditions. However, any uncertainty introduced is expected to be limited on the basis of the narrow recommended range.</p>                                                                                                                                                                            |
| $d_z$    | Total water body depth                | m                                         | <p style="text-align: center;"><b>Varies (calculated)</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends that the following equation be used to calculate total water body depth, consistent with NC DEHNR (1997):</p> $d_z = d_{wc} + d_{bs}$ <p>The following uncertainty is associated with this variable:</p> <p>(1) Calculation of this variable combines the concentrations associated with the two variables (<math>d_{wc}</math> and <math>d_{bs}</math>) being summed. Because most of the total water body depth (<math>d_z</math>) is made up of the depth of the water column (<math>d_{wc}</math>), and the uncertainties associated with <math>d_{wc}</math> are not expected to be significant, the total uncertainties associated with this variable, <math>d_z</math>, are also not expected to be significant.</p> |
| BS       | Benthic solids concentration          | g/cm <sup>3</sup><br>(equivalent to kg/L) | <p style="text-align: center;"><b>1.0</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends a default value of 1.0, consistent with U.S. EPA (1993a), which states that this value should be reasonable for most applications. The recommended default value is also consistent with other U.S. EPA (1993b and 1994) and NC DEHNR (1997) guidance.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended default value may not accurately represent site- and water body-specific conditions. Therefore, the variable <math>f_{wc}</math> may be under- or overestimated; the assumption that the under- or overestimation will be limited is based on the narrow recommended range.</p>                                                                                                        |

|---------------|--------------------------------------------------------|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\theta_{bs}$ | Bed sediment porosity                                  | $L_{\text{water}}/L_{\text{sediment}}$ | <p style="text-align: center;"><b>0.6</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends a default bed sediment porosity of 0.6 (by using a <i>BS</i> value of 1 g/cm<sup>3</sup> and a solid density (<math>\rho_s</math>) value of 2.65 kg/L, calculated by using the following equation (U.S. EPA 1993a):</p> $\theta_{bs} = 1 - BS / \rho_s$ <p>This is consistent with other U.S. EPA (1993b and 1994) guidance.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Calculation of this variable combines the uncertainties associated with the two variables (<i>BS</i> and <math>\rho_s</math>) used in the calculation. To the extent that the recommended default values of <i>BS</i> and <math>\rho_s</math> do not accurately represent site- and water body-specific conditions, <math>\theta_{bs}</math> will be under- or overestimated.</p> |
| $Kd_{bs}$     | Bed sediment/sediment pore water partition coefficient | L/kg                                   | <p style="text-align: center;"><b>Varies (see Appendix A-2)</b></p> <p>This variable is COPC-specific, and should be determined from the COPC tables in Appendix A-2.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The <math>Kd_{bs}</math> values in Appendix A-2 are based on default <i>OC</i> contents for sediment and soil. <math>Kd_{bs}</math> values based on default <i>OC</i> values may not accurately represent site- and water body-specific conditions and may under- or overestimate actual <math>Kd_{bs}</math> values. Uncertainty associated with this variable will be reduced if site- and water body-specific <i>OC</i> estimates are used to calculate <math>Kd_{bs}</math>.</p>                                                                                                                                                              |

## TABLE B-2-10

### FRACTION IN WATER COLUMN AND BENTHIC SEDIMENT (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 5 of 5)

#### REFERENCES AND DISCUSSION

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is cited as one of the sources of the range of  $Kd_s$  values and assumed  $OC$  values of 0.075 and 0.04 for surface water and sediment, respectively. This document is also cited as one of the sources of TSS. This document cites U.S. EPA (1993b) as its source of information. This document is also cited as the source of the equation for calculating total water body depth. No source of this equation was identified. This document is also cited as one of the reference source documents for the default value for bed sediment porosity. This document cites U.S. EPA (1993b) as its source of information. This document is also cited as one of the reference source documents for the default value for depth of the upper benthic layer. The default value is the midpoint of an acceptable range. This document cites U.S. EPA (1993b) as its source of information for the range of values for the depth of the upper benthic layer. This document is also cited as one of the reference source documents for the default bed sediment concentration.

U.S. EPA. 1993a. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November 1993.

This document is cited as one of the sources of the range of  $Kd_s$  values and assumed  $OC$  values of 0.075 and 0.04 for surface water and sediment, respectively. The generic equation for calculating partition coefficients (soil, surface water, and bed sediments) is as follows:  $Kd_{ij} = Koc * OC_i$ .  $Koc$  is a chemical-specific value; however,  $OC$  is medium-specific. The range of  $Kd_s$  values was based on an assumed  $OC$  value of 0.01 for soil.  $Kd_{sw}$  and  $Kd_{bs}$  values were estimated by multiplying the  $Kd_s$  values by 7.5 and 4, because the  $OC$  values for surface water and sediment are 7.5 and 4 times greater than the  $OC$  value for soil. This document also presents the equation for calculating bed sediment porosity ( $\theta_{bs}$ ); no source of this equation was identified. This document was also cited as the source for the range of the benthic solids concentration (BS); no original source of this range was identified. Finally, this document recommends that, in the absence of site-specific information, a TSS value of 1 to 10 be specified for parks and lakes, and a TSS value of 10 to 20 be specified in streams and rivers.

U.S. EPA. 1993b. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document is cited by NC DEHNR (1997) as the source of the TSS value. This document is also cited by NC DEHNR (1997) and U.S. EPA (1994) as the source of the default bed sediment porosity value and the equation used to calculate the variable, the default bed sediment concentration value, and the range for the depth of the upper benthic layer values.

U.S. EPA. 1994. *Draft Guidance for Performing Screening Level Risk Analyses at Combustor Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. April 15.

This document is cited as one of the reference source documents for the default value for bed sediment porosity. This document cites U.S. EPA (1993b) as its source of information. This document is also cited as one of the reference source documents for the default value for depth of the upper benthic layer. The default value is the midpoint of an acceptable range. This document cites U.S. EPA (1993b) as its source of information for the range of values for the depth of the upper benthic layer. This document is also cited as one of the reference source documents for the default benthic solids concentration.

**OVERALL TOTAL WATER BODY DISSIPATION RATE CONSTANT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 2)

| Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                     |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>This equation calculates the overall dissipation rate of COPCs in surface water, resulting from volatilization and benthic burial.</p> <p>Uncertainties associated with this equation include the following:</p> <p>(1) All of the variables in the equation in Table B-2-11 are site-specific. Therefore, the use of default values for any or all of these variables will contribute to the under- or overestimation of <math>k_{wt}</math>. The degree of uncertainty associated with the variable <math>k_b</math> is expected to be one order of magnitude at most and is associated with the estimation of the unit soil loss, <math>X_e</math>. Values for the variables <math>f_{wc}</math>, <math>k_v</math>, and <math>f_{bs}</math> are dependent on medium-specific estimates of medium-specific OC content. Because OC content can vary widely for different locations in the same medium, uncertainty associated with these three variables may be significant in specific instances.</p> |                                                                     |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Equation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                     |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Uncertainties associated with this variable include the following:</p> <p>(1) The default variable values recommended for use in the equation in Table B-2-10 may not accurately represent site-specific water body conditions. However, the range of several variables—including <math>d_{bs}</math>, <math>BS</math>, and <math>\theta_{sw}</math>—is moderate (factors of 5, 3, and 2, respectively); therefore, the degree of uncertainty associated with these variables is expected to be moderate. Other variables, such as <math>d_{wc}</math> and <math>d_z</math>, can be reasonably estimated on the basis of generally available information; therefore, the degree of uncertainty associated with these variables is expected to be relatively small.</p> <p>(2) The largest degree of uncertainty may be introduced by the default medium-specific OC content values. OC content values are often not readily available and can vary widely for different locations in the same medium. Therefore, the degree of uncertainty may be significant in specific instances.</p> |

Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of <math>k_b</math>.</li> <li>(2) The degree of uncertainty associated with each of these variables is as follows: (1) <math>X_e</math>—about one order of magnitude at most, (2) <math>BS</math>, <math>d_{bs}</math>, <math>Vf_x</math>, <math>TSS</math>, and <math>A_w</math>—limited because of the narrow recommended ranges for these variables or because resources to estimate variable values are generally available, and (3) <math>A_L</math> and <math>SD</math>—very site-specific and degree of uncertainty unknown.</li> </ol>                                                                                                                                        |

TABLE B-2-12

**WATER COLUMN VOLATILIZATION LOSS RATE CONSTANT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 4)

**Description**

This equation calculates the water column of COPCs loss resulting from volatilization. Uncertainties associated with this equation include the following:

- (1) All of the variables in Table B-2-12 are site-specific. Therefore, the use of default values for any or all of these variables will contribute to the under- or over estimation of  $k_v$ . The degree of uncertainty associated with the variables  $d_{wc}$ ,  $d_{bs}$ ,  $d_z$ , and  $TSS$  are expected to be minimal either because information necessary to estimate these variables is generally available or because the range of probable values is narrow. Values for the variables  $K_v$  and  $Kd_{sw}$  are dependent on medium-specific estimates of  $OC$  content. Because  $OC$  content can vary widely for different locations in the same medium, uncertainty associated with these two variables may be significant in specific instances.

**Equation**

$$k_v = \frac{K_v}{d_z \cdot (1 + Kd_{sw} \cdot TSS \cdot 10^{-6})}$$

**For mercury modeling:**

The water column volatilization loss rate constant is calculated for divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) using their respective fate and transport parameters .

|----------|----------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $K_v$    | Overall COPC transfer rate coefficient | m/yr  | <p style="text-align: center;"><b>Varies (calculated - Table B-2-13)</b></p> <p>This variable is COPC- and site-specific, and is calculated by using the equation in Table B-2-13.</p> <p>Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) All of the variables in Table B-2-13—except <math>R</math>, the universal gas constant, which is well-established—are site-specific. Therefore, the use of default values, for any or all these variables, could contribute to the under- or overestimation of <math>K_v</math>.</li> <li>(2) The degree of uncertainty associated with the variables <math>H</math> and <math>T_{wk}</math> is expected to be minimal; values for <math>H</math> are well-established, and average water body temperature, <math>T_{wk}</math>, will likely vary less than 10 percent of the default value.</li> <li>(3) The uncertainty associated with the variables <math>K_L</math> and <math>K_G</math> is attributable largely to medium-specific estimates of <math>OC</math> content. Because <math>OC</math> content values can vary widely for different locations in the same medium, the use of default values may generate significant uncertainty in specific instances. Finally, the origin of the recommended <math>\theta</math> value is unknown; therefore, the degree of associated uncertainty is also unknown.</li> </ol> |
| $d_{wc}$ | Depth of water column                  | m     | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific and should be an average annual value.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Use of default values for depth of water column, <math>d_{wc}</math>, may not accurately reflect site-specific conditions, especially for those water bodies for which depth of water column information is unavailable or outdated. Therefore, use of default <math>d_{wc}</math> values may contribute to the under- or overestimation of total water body COPC concentration, <math>C_{wtot}</math>. However, the degree of under- or overestimation is not expected to be significant.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| $d_{bs}$ | Depth of upper benthic sediment layer  | m     | <p style="text-align: center;"><b>0.03</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends a default upper-benthic sediment depth of 0.03 meter, which is based on the center of this range cited by U.S. EPA (1993b). This is consistent with U.S. EPA (1994) and NC DEHNR (1997).</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Use of default values for depth of upper benthic layer, <math>d_{bs}</math>, may not accurately represent site-specific water body conditions. However, any uncertainty introduced is expected to be limited, based on the narrow recommended range.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Variable  | Description                                             | Units | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|---------------------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $d_z$     | Total water body depth                                  | m     | <p style="text-align: center;"><b>Varies (calculated)</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends that the following equation be used to calculate total water body depth, consistent with NC DEHNR (1997):</p> $d_z = d_{wc} + d_{bs}$ <p>The following uncertainty is associated with this variable:</p> <p>(1) Calculation of this variable combines the concentrations associated with the two variables (<math>d_{wc}</math> and <math>d_{bs}</math>) being summed. Because most of the total water body depth (<math>d_z</math>) is made up of the depth of the water column (<math>d_{wc}</math>), and the uncertainties associated with <math>d_{wc}</math> are not expected to be significant, the total uncertainties associated with this variable, <math>d_z</math>, are also not expected to be significant.</p> |
| $Kd_{sw}$ | Suspended sediments/surface water partition coefficient | L/kg  | <p style="text-align: center;"><b>Varies (see Appendix A-2)</b></p> <p>This variable is COPC-specific and should be determined from the COPC tables in Appendix A-3.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The values contained in Appendix A-2 for <math>Kd_{sw}</math> are calculated on the basis of default OC contents for surface water and soil. <math>Kd_{sw}</math> values based on default values may not accurately reflect site-and water body-specific conditions and may under- or overestimate actual <math>Kd_{sw}</math> values. Uncertainty associated with this variable will be reduced if site-specific and medium-specific OC estimates are used to calculate <math>Kd_{sw}</math>.</p>                                                                                                |
| TSS       | Total suspended solids concentration                    | mg/L  | <p style="text-align: center;"><b>2 to 300</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends the use of site- and waterbody specific measured values, representative of long-term average annual values for the water body of concern (see Chapter 3). A value of 10 mg/L was cited by NC DEHNR (1997), U.S. EPA (1993a), and U.S. EPA (1993b) in the absence of site-specific measured data.</p> <p>The following uncertainty is associated with this variable:</p> <p>Limitation on measured data used for determining a water body specific total suspended solids (TSS) value may not accurately reflect site- and water body-specific conditions long term. Therefore, the TSS value may contribute to the under-or overestimation of <math>f_{wc}</math>.</p>                                                                 |
| $10^{-6}$ | Units conversion factor                                 | kg/mg |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## TABLE B-2-12

### WATER COLUMN VOLATILIZATION LOSS RATE CONSTANT (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 4 of 4)

#### REFERENCES AND DISCUSSION

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is cited as the source of the equation for calculating total water body depth. No source of this equation was identified. This document is also cited as one of the sources of the range of  $Kd_s$  values and an assumed  $OC$  value of 0.075 for surface water. This document is also cited as one of the sources of  $TSS$ . This document cites U.S. EPA (1993b) as its source of information.

U.S. EPA. 1993a. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November 1993.

This document is cited as one of the sources of the range of  $Kd_s$  values and assumed  $OC$  content value of 0.075 for surface water. The generic equation for calculating partition coefficients (soil, surface water, and bed sediments) is as follows:  $Kd_{ij} = K_{ocj} OC_i$ .  $K_{oc}$  is a chemical-specific value; however,  $OC$  is medium-specific. The range of  $Kd_s$  values was based on an assumed  $OC$  value of 0.01 for soil. This document is one of the sources cited that assumes an  $OC$  value of 0.075 for surface water. Therefore, the  $Kd_{sw}$  value was estimated by multiplying the  $Kd_s$  values by 7.5, because the  $OC$  value for surface water is 7.5 times greater than the  $OC$  value for soil.

U.S. EPA. 1993b. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document is cited by U.S. EPA (1994) and NC DEHNR (1997) as the source of the range and default value for the depth of the upper benthic layer ( $d_{bs}$ ). This document is also cited by NC DEHNR (1997) as the source of the  $TSS$  value.

U.S. EPA. 1994. *Draft Guidance for Performing Screening Level Risk Analysis at Combustion Facility Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facility*. April 15.

This document is cited as one of the reference source documents for the default value of the depth of the upper benthic layer. The default value is the midpoint of an acceptable range. This document cites U.S. EPA (1993b) as its source of information.

TABLE B-2-13

**OVERALL COPC TRANSFER RATE COEFFICIENT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

**Page (1 of 4)**

**Description**

This equation calculates the overall transfer rate of contaminants from the liquid and gas phases in surface water.

Uncertainties associated with this equation include the following:

- (1) All of the variables in Table B-2-13—except  $R$ , the universal gas constant, which is well-established—are site-specific. Therefore, the use of any or all of these variables will contribute to the under- or overestimation of  $K_v$ . The degree of uncertainty associated with the variables  $H$  and  $T_{wk}$  is expected to be minimal; values for  $H$  are well-established, and average water body temperature will likely vary less than 10 percent of the default value. The uncertainty associated with the variables  $K_v$  and  $K_G$  is attributable largely to medium-specific estimates of  $OC$  content. Because  $OC$  content values can vary widely for different locations in the same medium, the use of default values may generate significant uncertainty in specific instances.

**Equation**

$$K_v = \left[ K_L^{-1} + \left( K_G \cdot \frac{H}{R \cdot T_{wk}} \right)^{-1} \right]^{-1} \cdot \theta^{(T_{wk} - 293)}$$

**For mercury modeling:**

The overall COPC transfer rate coefficient is calculated for divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) using their respective fate and transport parameters .

| Variable | Description                            | Units | Value |
|----------|----------------------------------------|-------|-------|
| $K_v$    | Overall COPC transfer rate coefficient | m/yr  |       |

## TABLE B-2-13

### OVERALL COPC TRANSFER RATE COEFFICIENT (SURFACE WATER AND SEDIMENT EQUATIONS)

Page (4 of 4)

#### REFERENCES AND DISCUSSION

U.S. EPA. 1993a. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document is the reference source for the equation in Table B-2-12, including the use of the temperature correction fraction ( $\theta$ ).

This document is also cited by U.S. EPA (1994) as the source of the  $T_{wk}$  value of 298 K (298 K = 25°C) and the default  $\theta$  value of 1.026.

U.S. EPA. 1993b. *Addendum to Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Solid Waste and Office Research and Development. Washington, D.C. November 10.

This document recommends the  $T_{wk}$  value of 298 K (298 K = 25 °C) and the value  $\theta$  of 1.026. No source was identified for these values.

U.S. EPA 1994. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document is cited as the reference source for water body temperature ( $T_{wk}$ ) and temperature correction factor ( $\theta$ ). This document apparently cites U.S. EPA (1993a) as its source of information.

TABLE B-2-14

**LIQUID-PHASE TRANSFER COEFFICIENT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

**(Page 1 of 5)**

**Description**

This equation calculates the rate of contaminant transfer from the liquid phase for a flowing or quiescent system.

Uncertainties associated with this equation include the following:

- (1) Minimal or insignificant uncertainty is assumed to be associated with the following six variables:  $D_w$ ,  $d_z$ ,  $\rho_a$ ,  $\rho_w$ , and  $\mu_w$ .
- (2) No original sources were identified for equations used to derive recommended values or specific recommended values for the following three variables:  $C_d$ ,  $k$ , and  $d_z$ . Therefore, the degree and duration of any uncertainties associated with these variables is unknown.
- (3) Uncertainties associated with the variable  $W$  are site-specific.

**Equation**

For flowing streams or rivers

$$K_L = \sqrt{\frac{10^{-4} \cdot D_w \cdot u}{d_z}} \cdot 3.1536 \times 10^7$$

For quiescent lakes or ponds

$$K_L = (C_d^{0.5} \cdot W) \cdot \left( \frac{\rho_a}{\rho_w} \right)^{0.5} \cdot \left( \frac{k^{0.33}}{\lambda_z} \right) \cdot \left( \frac{\mu_w}{\rho_w \cdot D_w} \right)^{-0.67} \cdot 3.1536 \times 10^7$$

**For mercury modeling:**

The liquid phase transfer coefficient is calculated for divalent mercury ( $\text{Hg}^{2+}$ ) and methyl mercury (MHg) using their respective fate and transport parameters.

| Variable | Description                       | Units              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------|-----------------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $K_L$    | Liquid-phase transfer coefficient | m/yr               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| $D_w$    | Diffusivity of COPC in water      | cm <sup>2</sup> /s | <p style="text-align: center;"><b>Varies (see Appendix A-2)</b></p> <p>This variable is COPC-specific and should be determined from the COPC physical and chemical parameter tables in Appendix A-2.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The default <math>D_w</math> values may not accurately represent the behavior of COPCs under water body-specific conditions. However, the degree of uncertainty is expected to be minimal.</p>                                 |
| $u$      | Current velocity                  | m/s                | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Sources of values for this variable are reasonably available for most large surface water bodies. Estimated values for this variable be necessary for smaller water bodies; uncertainty will be associated with these estimates. The degree of uncertainty associated with this variable is not expected to be significant.</p> |

TABLE B-2-14

**LIQUID-PHASE TRANSFER COEFFICIENT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 3 of 5)

| Variable             | Description               | Units    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $d_z$                | Total water body depth    | m        | <p style="text-align: center;"><b>Varies (calculated)</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends that this value be calculated by using the following equation, consistent with U.S. EPA (1994):</p> $d_z = d_{wc} + d_{bs}$ <p>No reference was cited for this recommendation.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) Calculation of this variable combines the concentrations associated with the two variables (<math>d_{wc}</math> and <math>d_{bs}</math>) being summed. Because most of the total water body depth (<math>d_z</math>) is made up of the depth of the water column (<math>d_{wc}</math>), and the uncertainties associated with <math>d_{wc}</math> are not expected to be significant, the total uncertainties associated with this variable, <math>d_z</math>, are also not expected to be significant.</p> |
| $3.1536 \times 10^7$ | Units conversion constant | s/yr     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| $C_d$                | Drag coefficient          | unitless | <p style="text-align: center;"><b>0.0011</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends a default value of 0.0011, consistent with U.S. EPA (1993a; 1993b; 1994) and NC DEHNR (1997).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The original source of this variable value is unknown. Therefore, any uncertainties associated with its use are also unknown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| $W$                  | Average annual wind speed | m/s      | <p style="text-align: center;"><b>3.9</b></p> <p>Consistent with U.S. EPA (1990), U.S. EPA OSW recommends a default value of 3.9 m/s. See Chapter 3 for guidance regarding the references and methods used to determine site-specific values for air dispersion modeling.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## TABLE B-2-14

### LIQUID-PHASE TRANSFER COEFFICIENT (SURFACE WATER AND SEDIMENT EQUATIONS)

(Page 5 of 5)

#### REFERENCES AND DISCUSSION

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is cited as one of the sources of the range of  $D_w$  values and assumed  $C_d$ ,  $\rho_a$ ,  $\rho_w$ ,  $k$ ,  $\lambda_z$ , and  $\mu_w$  values of 0.0011,  $1.2 \times 10^{-3}$ , 1, 0.4, 4, and  $1.69 \times 10^{-2}$ , respectively. This document cites (1) Weast (1979) as its source of information regarding  $\rho_a$ ,  $\rho_w$ , and  $\mu_w$ ; and (2) U.S. EPA (1993a) as its source of information regarding  $C_d$ ,  $k$ , and  $d_z$ .

U.S. EPA. 1993a. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste and Office of Research and Development. Washington, D.C. September 24.

This document is cited by U.S. EPA (1994) and NC DEHNR (1997) as the source of the recommended drag coefficient ( $C_d$ ) value of 0.0011 and the recommended von Karman's constant ( $k$ ) value of 0.4. The original sources of variable values are not identified.

U.S. EPA. 1993b. *Addendum to Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Solid Waste and Office of Research and Development. Washington, D.C. November 10.

This document recommends a value of 0.0011 for the drag coefficient ( $C_d$ ) variable or a value of 0.4 for von Karman's constant ( $k$ ). No sources are cited for these values.

U.S. EPA. 1994. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document is cited as one of the sources of the range of  $D_w$  values and assumed  $C_d$ ,  $\rho_a$ ,  $\rho_w$ ,  $k$ ,  $\lambda_z$ , and  $\mu_w$  values of 0.0011,  $1.2 \times 10^{-3}$ , 1, 0.4, 4, and  $1.69 \times 10^{-2}$ , respectively. This document cites (1) Weast (1979) as its source of information regarding  $\rho_a$ ,  $\rho_w$ , and  $\mu_w$ ; and (2) U.S. EPA (1993a) as its source of information regarding  $C_d$ ,  $k$ , and  $d_z$ .

Weast, R. C. 1979. *CRC Handbook of Chemistry and Physics*. 60th ed. CRC Press, Inc. Cleveland, Ohio.

This document is cited as the source of  $\rho_a$ ,  $\rho_w$ , and  $\mu_w$  variables of  $1.2 \times 10^{-3}$ , 1, and  $1.69 \times 10^{-2}$ , respectively.

(Page 4 of 4)

#### REFERENCES AND DISCUSSION

NC DEHNR. 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is cited as one of the sources of the variables  $\rho_a$ ,  $k$ ,  $\lambda_z$ , and  $\mu_a$  values of  $1.2 \times 10^{-3}$ , 0.4, 4, and  $1.81 \times 10^{-4}$ , respectively. This document cites (1) Weast (1979) as its source of information for  $\rho_a$  and  $\mu_a$ , and (2) U.S. EPA (1993a) as its source of information for  $k$  and  $\lambda_z$ .

U.S. EPA. 1993a. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustion Emissions*. Working Group Recommendations. Office of Solid Waste, and Office of Research and Development. Washington, D.C. September 24.

This document is cited by U.S. EPA (1994) and NC DEHNR (1997) as the source of (1) the recommended drag coefficient ( $C_d$ ) value of 0.0011, (2) the recommended von Karman's constant ( $k$ ) value of 0.4, and (3) the recommended dimensionless viscous sublayer thickness ( $\lambda_z$ ) value of 4. The original sources of these variable values are not identified.

U.S. EPA. 1993b. *Addendum to Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustion Emissions*. External Review Draft. Office of Solid Waste, and Office of Research and Development. Washington, D.C. November 10.

This document recommends (1) a value of 0.0011 for the drag coefficient ( $C_d$ ) variable, (2) a value of 0.4 for von Karman's constant ( $K$ ), and (3) a value of 4 for the dimensionless viscous sublayer thickness ( $\lambda_z$ ) variable. The original sources of the variable values are not identified.

U.S. EPA. 1994. *Revised Draft Guidance for Performing Screening Level Risk Analyses at Combustion Facilities Burning Hazardous Wastes. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. Office of Emergency and Remedial Response. Office of Solid Waste. December 14.

This document is cited as one of the sources of the variables  $\rho_a$ ,  $k$ ,  $\lambda_z$ , and  $\mu_a$  values of  $1.2 \times 10^{-3}$ , 0.4, 4, and  $1.81 \times 10^{-4}$ , respectively. This document cites (1) Weast (1979) as its source of information for  $\rho_a$  and  $\mu_a$ , and (2) U.S. EPA (1993a) as its source of information for  $k$  and  $\lambda_z$ .

Weast, R.C. 1979. *CRC Handbook of Chemistry and Physics*. 60th ed. CRC Pres, Inc. Cleveland, Ohio. This document is cited as the source of  $\rho_a$ ,  $\rho_w$ , and  $\mu_a$  variables of  $1.2 \times 10^{-3}$ , 1, and  $1.69 \times 10^{-2}$ , respectively.

TABLE B-2-16

**BENTHIC BURIAL RATE CONSTANT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 5)

**Description**

This equation calculates the constant for water column loss constant due to burial in benthic sediment.

Uncertainties associated with this equation include the following:

- (1) All of the variables in Table B-2-16 are site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of  $K_b$ . The degree of uncertainty associated with each of these variables is as follows: (a)  $X_e$ —about one order of magnitude at the most, (b)  $BS$ ,  $d_{bs}$ ,  $Vf_x$ ,  $TSS$ , and  $A_w$ —limited because of the narrow recommended ranges for these variables or because resources to estimate variable values are generally available, (c)  $A_L$  and  $SD$ —very site-specific, degree of uncertainty unknown.

Based on the possible ranges for the input variables to this equation, values of  $k_b$  can range over about one order of magnitude.

**Equation**

$$k_b = \left( \frac{X_e \cdot A_L \cdot SD \cdot 10^3 - Vf_x \cdot TSS}{A_w \cdot TSS} \right) \left( \frac{TSS \cdot 10^{-6}}{BS \cdot d_{bs}} \right)$$

| Variable | Description                  | Units                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| $A_L$    | Total watershed area receiving deposition       | m <sup>2</sup>     | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific (see Chapter 4). Uncertainties associated with this variable are site-specific.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $SD$     | Sediment delivery ratio                         | unitless           | <p style="text-align: center;"><b>Varies (calculated - Table B-2-8)</b></p> <p>This variable is site-specific and is calculated by using the equation in Table B-2-8.</p> <p>Uncertainties associated with this variable include the following:</p> <ol style="list-style-type: none"> <li>(1) The default values for empirical intercept coefficient, <math>a</math>, recommended for use in the equation in Table B-2-8, are average values based on various studies of sediment yields from various watersheds. Therefore, these default values may not accurately represent site-specific watershed conditions. As a result, use of these default values may contribute to under- or overestimation of the benthic burial rate constant, <math>k_b</math>.</li> <li>(2) The default value for empirical slope coefficient, <math>b</math>, recommended for use in the equation in Table B-2-8 is based on a review of sediment yields from various watersheds. This single default value may not accurately represent site-specific watershed conditions. As a result, use of this default value may contribute to under- or overestimation of <math>k_b</math>.</li> </ol> |
| $10^3$   | Units conversion factor                         | g/kg               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| $Vf_x$   | Average volumetric flow rate through water body | m <sup>3</sup> /yr | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific and should be an annual average value.</p> <p>The following uncertainty is associated with this variable:</p> <ol style="list-style-type: none"> <li>(1) Use of default average volumetric flow rate, <math>Vf_x</math>, values may not accurately represent site-specific water body conditions. Therefore, the use of such default values may contribute to the under- or overestimation of <math>k_b</math>. However, it is expected that the uncertainty associated with this variable will be limited, because resources such as maps, aerial photographs, and gauging station measurements—from which average volumetric flow rate through water body, <math>Vf_x</math>, can be estimated—are generally available.</li> </ol>                                                                                                                                                                                                                                                                                                                                         |

TABLE B-2-16

**BENTHIC BURIAL RATE CONSTANT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 3 of 5)

| Variable           | Description                          | Units                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|--------------------------------------|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TSS                | Total suspended solids concentration | mg/L                                            | <p style="text-align: center;"><b>2 to 300</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends the use of site- and waterbody specific measured values, representative of long-term average annual values for the water body of concern (see Chapter 3). A value of 10 mg/L was cited by NC DEHNR (1997), U.S. EPA (1993a), and U.S. EPA (1993b) in the absense of site-specific measured data.</p> <p>The following uncertainty is associated with this variable:</p> <p style="padding-left: 40px;">Limitation on measured data used for determining a water body specific total suspended solids ( TSS) value may not accurately reflect site- and water body-specific conditions long term. Therefore, the TSS value may contribute to the under-or overestimation of <math>f_{wc}</math>.</p> |
| $A_w$              | Water body surface area              | m <sup>2</sup><br>(average for the entire year) | <p style="text-align: center;"><b>Varies (site-specific)</b></p> <p>This variable is site-specific (see Chapter 4), and should be an average annual value. The units of this variable are presented as they are because the value selected is assumed to represent an average value for the entire year. Uncertainties associated with this variable are site-specific, and expected to be limited, because maps, aerial photographs —and other resources from which water body surface area, <math>A_w</math>, can be measured—are readily available.</p>                                                                                                                                                                                                                                                        |
| $1 \times 10^{-6}$ | Units conversion factor              | kg/mg                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| BS                 | Benthic solids concentration         | g/cm <sup>3</sup><br>(equivalent to kg/L)       | <p style="text-align: center;"><b>1.0</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends a default value of 1.0, consistent with U.S. EPA (1993b), which states that this value should be reasonable for most applications. The recommended default value is also consistent with other U.S. EPA (1993a; 1993b; 1994) guidance.</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended default benthic solids concentration, BS, value may not accurately represent site-specific water body conditions. Therefore, use of this default value may contribute to the under- or overestimation of <math>k_b</math>.</p>                                                                                                                                      |

TABLE B-2-16

**BENTHIC BURIAL RATE CONSTANT  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

| Variable | Description                           | Units | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|---------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $d_{bs}$ | Depth of upper benthic sediment layer | m     | <p><b>0.03</b></p> <p>This variable is site-specific. U.S. EPA OSW recommends a default upper-benthic sediment depth of 0.03 meter, which is based on the center of this range cited by U.S. EPA (1993a; 1993b). This range is consistent with U.S. EPA (1994).</p> <p>The following uncertainty is associated with this variable:</p> <p>(1) The recommended default value for depth of upper benthic layer, <math>d_{bs}</math>, may not accurately represent site-specific water body conditions. Therefore, use of this default value may contribute to the under- or overestimation of <math>k_b</math>. However, the degree of uncertainty associated with this variable is expected to be limited because of the narrow recommended range.</p> |

#### REFERENCES AND DISCUSSION

NC DEHNR 1997. *NC DEHNR Protocol for Performing Indirect Exposure Risk Assessments for Hazardous Waste Combustion Units*. January.

This document is cited as one of the sources of the range of all recommended specific  $BS$  and  $d_{bs}$  values, and the recommended  $TSS$  value. This document cites U.S. EPA (1993a) as its source.

U.S. EPA. 1993a. *Addendum: Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. Working Group Recommendations. Office of Solid Waste, and Office of Research and Development. Washington, D.C. September 24.

This document is cited by U.S. EPA (1994) and NC DEHNR (1997) as the source of (1) the  $TSS$  value, (2) the range and recommended  $BS$  value, and (3) the range and recommended depth of upper benthic layer ( $d_{bs}$ ) value.

U.S. EPA 1993b. *Addendum to the Methodology for Assessing Health Risks Associated with Indirect Exposure to Combustor Emissions*. External Review Draft. Office of Research and Development. Washington, D.C. November.

This document states that the upper benthic sediment depth,  $d_{bs}$ , representing the portion of the bed in equilibrium with the water column, cannot be precisely specified. However, the document states that values from 0.01 to 0.05 meter would be appropriate. This document also recommends a  $TSS$  value of 10 mg/L and a specific benthic solids concentration ( $BS$ ) value.

U.S. EPA 1994. *Draft Guidance for Performing Screening Level Risk Analyses at Combustor Facilities Burning Hazardous Waste. Attachment C, Draft Exposure Assessment Guidance for RCRA Hazardous Waste Combustion Facilities*. April 15.

This document is cited as one of the reference sources for the  $d_{bs}$  value. The recommended value is the midpoint of an acceptable range. This document is also cited as one of the reference source documents for the default  $BS$  value. This document cites U.S. EPA (1993a) as its source.

TABLE B-2-17

**TOTAL WATER COLUMN CONCENTRATION  
(SURFACE WATER AND SEDIMENT EQUATIONS)**

(Page 1 of 4)

**Description**

This equation calculates the total water column concentration of COPCs; this includes both dissolved COPCs and COPCs sorbed to suspended solids.

Uncertainties associated with this equation include the following:

- (1) All of the variables in Table B-2-17 are COPC- and site-specific. Therefore, the use of default values rather than site-specific values, for any or all of these variables, will contribute to the under- or overestimation of  $C_{wctot}$ .

The degree of uncertainty associated with the variables  $d_{wc}$  and  $d_{bs}$  is expected to be minimal either because information for estimating a variable ( $d_{wc}$ ) is generally available or because the probable range for a variable ( $d_{bs}$ ) is narrow. The uncertainty associated with the variables  $f_{wc}$  and  $C_{wtot}$  is associated with estimates of OC content. Because OC content values can vary widely for different locations in the same medium, the uncertainty associated with using default OC values may be significant in specific cases.

**Equation**

$$C_{wctot} = f_{wc} \cdot C_{wtot} \cdot \frac{d_{wc} + d_{bs}}{d_{wc}}$$

**For mercury modeling:**

Total water column concentration is calculated for divalent mercury ( $Hg^{2+}$ ) and methyl mercury (MHg) using their respective  $C_{wtot}$  values and  $f_{wc}$  values.

| Variable    | Description                              | Units | Value |
|-------------|------------------------------------------|-------|-------|
| $C_{wctot}$ | Total COPC concentration in water column | mg/L  |       |
